1 Motivation

For most of the world’s population, important financial tools are inaccessible. This is exemplified by the fact that two people can share the same education, perform the same work, and put in the same amount of effort, yet not have the same development possibilities. One could have access to a share of the global economy’s growth, while the other may be left out.

It’s brutal and unfair. Until now, borders have limited human development. With the advent of blockchain technology, we are amid a global switch in the financial foundation we use as a society to trade and transact. At the forefront of this transformation, we present a new solution to equalize the playing field by bringing the world’s assets to the blockchain. This solution allows anyone to access and participate in new financial markets and take control of their own financial destiny, paving the way for a new mantra: Tokenize Everything.

2 Introduction

This document (the “Indigo paper”) presents the Indigo Protocol (the “protocol” or “Indigo”), a synthetic assets protocol built for Cardano¹. Combining the benefits of a white paper² and a yellow paper³, the Indigo paper provides both a high-level and detailed protocol specification for educating the Indigo community. The Indigo paper serves as the basis to introduce Indigo and kickstart complete community management.

Indigo has been committed to a [Fair Launch](#) to bootstrap the protocol from the ground up. As part of this initiative, no minting, pre-sale, or distribution of tokens related to the protocol have been undertaken. This ensures that starting from launch, Indigo will be community managed.

2.1 Synthetic Assets

Indigo creates synthetic assets which are known in the protocol as iAssets (i.e., “Indigo Assets”). iAssets are cryptocurrency assets that derive their prices from tracked assets. Prices of iAssets are influenced via protocol rules with the intention of matching the prices of the tracked assets. One example of an iAsset is iBTC, representing a synthetic version of Bitcoin (BTC); it is designed to mimic the price action of BTC – an asset that lives in separate ecosystem than Indigo.

¹Cardano is a public blockchain that supports smart contracts and custom tokens utilizing an eUTXO architecture, an extension of UTXO.

²A [white paper](#) is a marketing tool typically used to attract investors.

³A [yellow paper](#) typically contains complete specification details.

2.2 Indigo Protocol

Indigo is a decentralized synthetics protocol for on-chain exposure to assets with publicly verifiable prices. Using Cardano Plutus⁴ smart contracts, the protocol enables the creation of iAssets. Prices of iAssets are soft pegged⁵ to external tracked assets; iAssets are overcollateralized in the form of a decentralized Collateralized Debt Position (“CDP”). The protocol enforces liquidations to ensure iAssets always maintain overcollateralization, meaning the value of the collateral in the CDP exceeds the intended value of the iAsset. In the event of a CDP becoming undercollateralized, a liquidation reestablishes overcollateralization by confiscating the collateral of the undercollateralized CDP and replacing it with another user’s overcollateralized CDP.

While minting an iAsset requires opening a CDP, after iAssets are minted they are freely exchangeable. Anyone with a Cardano wallet can send or receive iAssets, regardless of whether they have an open CDP.

2.3 Benefits of iAssets

Users can gain some benefits of owning an asset without being required to obtain or own the asset themselves. This can be useful in cases where assets are difficult for a user to obtain or for assets that live elsewhere yet users desire to utilize on the Cardano blockchain.

iAssets can be used as building pieces to be included in a wider financial strategy. This could include being part of derivative contracts or constructing a widely diversified portfolio in one easy to use system. Users can make trades without requiring the underlying supply. For example, more iAsset could exist than total supply of the real asset, allowing for leveraged trades that wouldn’t be possible to be settled using the real underlying assets.

iAssets have the following properties:

- Tracking different type of assets and statistics; which allows the creation of many new asset classes for emerging industries.
- No custodians; iAsset creation is fully decentralized.
- Low barrier to entry; anyone with cryptocurrency can use Indigo to mint new synthetic assets or buy and trade them on the open market.
- Composability; iAssets can be used as a lego block, enabling their integration into a larger financial ecosystem.

Table 1: Examples of possible iAssets

Name	Description
iBTC	Tracks the price of BTC on the Bitcoin blockchain
iETH	Tracks the price of ETH on the Ethereum blockchain
iUSD	Tracks the price of dollar-denominated stablecoins on any blockchain
iCPI	Tracks the change of the Consumer Price Index over time

Generally, an iAsset names begin with the letter “i,” followed by the name of the tracked asset.

2.3.1 Obtaining iAssets

There are two ways to obtain iAssets:

- **Buying iAssets** – Users directly purchase iAssets via an exchange (centralized or decentralized), thus gaining exposure without having to request any loan.
- **Minting iAssets** – Users make interest-free, overcollateralized loans against their cryptocurrency assets.

Users can buy iAssets from any exchange that has available supply. After buying an iAsset, the user gains full control of the iAsset and can reap benefits from price possible appreciation. Users can be assured that iAssets maintain their intended pegged prices due to Indigo’s liquidation process.

The second way for users to obtain iAssets is by minting them within the Indigo Web App by depositing collateral and creating a loan.

⁴Plutus is a smart contract platform for Cardano.

⁵A soft peg is a strategy of maintaining the value of an asset against another asset by utilizing an exchange rate mechanism.

⁵The Consumer Price Index is a measure of the average change over time in the prices of goods and services.

2.4 Collateralized Debt Positions

Every iAsset is backed by collateral held in a Collateralized Debt Position (a “CDP”). A CDP is created by a user locking collateral (a minimum of 10 ADA) into Indigo to mint a new iAsset. An iAsset is borrowed against the **collateral**, creating a **debt**, and this **position** is watched by liquidators to ensure overcollateralization.

The value of the collateral in a CDP should always exceed a governance-based Minimum Collateral Ratio (a “MCR”). Each iAsset type has its own MCR. Both the value of the collateral and iAsset price can fluctuate over time, potentially causing a CDP to become undercollateralized. A CDP is considered undercollateralized when its collateral ratio (the “CR”) falls below the iAsset’s MCR. The CR is the ratio of the collateral value relative to the minted iAsset value, and can be calculated using the formula:

$$c = \frac{a}{md}$$

or:

$$c = \frac{ab}{mp}$$

Where:

- c is the CR used to determine solvency
- a is the amount of ADA locked in the CDP
- b is the dollar-denominated price of ADA
- p is the dollar-denominated price of the iAsset’s tracked asset
- d is the ADA-denominated price of the iAsset’s tracked asset
- m is the amount of iAsset minted from the CDP

When CR drops below MCR, the CDP is considered insolvent and eligible for being frozen, which can then lead to [liquidation](#) to ensure the reestablishment of solvency.

2.4.1 CDP and iAsset Example

As an example, assume Violet wants to mint 100 iDOT (m). DOT is trading for \$15 (p). Violet has 2,000 ADA (a) she’s willing to use as collateral to borrow iDOT. ADA is trading for \$1.28 (b).

Violet deposits 2,000 ADA into Indigo to mint 100 iDOT. A CDP is created consisting of 2,000 ADA. Violet now owns 100 iDOT and owes 100 iDOT to Indigo. Violet can still earn [staking rewards](#) from her 2,000 ADA, but cannot transfer it because it now is used as collateral. To regain control of her ADA, Violet must return 100 iDOT.

Violet’s CR is ~171%:

$$c = \frac{ab}{mp} \therefore \frac{2000 \times 1.28}{100 \times 15} = \sim 1.71$$

As the price of either DOT or ADA changes, CR changes too. When CR drops below the iDOT’s MCR, Violet’s CDP is subject to liquidation.

If the price of ADA increases to \$1.40 (b) and DOT increases to \$19 (p), then Violet’s CR drops to ~147%:

$$\frac{2000 \times 1.4}{100 \times 19} = \sim 1.47$$

If the iDOT MCR was 150%, Violet’s CDP could be liquidated. Upon liquidation, Violet would lose her 2,000 ADA collateral deposit. Violet could still have her 100 iDOT, worth \$1,900 (\$19 x 100). The 2,000 ADA she lost would be worth \$2,800 (\$1.40 x 2000). Therefore, Violet could have lost \$900 of value (\$2,800 - \$1,900).

To have prevented liquidation, Violet needed to either add more ADA into her CDP to increase its CR, or close the CDP by returning the 100 iDOT she borrowed.

2.4.2 CDP Actions and States

Several actions can be taken against a CDP by users of the protocol:

- **Open Position** – Creates a CDP by a user depositing a minimum of 10 ADA as collateral, and associates it with an iAsset type that can be minted. The user who creates the CDP becomes the CDP's owner.
- **Deposit Collateral** – An owner can increase CR by depositing more collateral.
- **Withdraw Collateral** – An owner can lower CR by withdrawing part or all the collateral. Collateral cannot be withdrawn if it brings CR below the iAsset's MCR. If a CDP has no debt (i.e., no minted iAsset) and all collateral is withdrawn, then the CDP is closed.
- **Borrow iAsset** – An owner can lower CR by minting an iAsset. This increases the amount of debt against the CDP. More iAsset cannot be minted if it brings CR below the iAsset's MCR.
- **Repay Debt** – An owner can increase the CR by repaying debt in the form of iAsset. When the debt is repaid, the iAsset is burned (i.e., destroyed). More iAsset cannot be burned than debt owed by the CDP.
- **Freeze** – If CR is below the iAsset's MCR, any user can submit a transaction for that CDP to be frozen. Upon freezing, a CDP is no longer usable or interactable by its former owner. The former owner loses all access and rights to the CDP.
- **Liquidate** – If a CDP is frozen, any user can submit a transaction for that CDP to be liquidated. Upon liquidation, CDP debt is repaid by withdrawing iAsset from a [Stability Pool](#). As debt is repaid, collateral is withdrawn from the CDP. If all debt is repaid, then all collateral is withdrawn, and the CDP is closed.
- **Merge** – If two or more CDPs are frozen, any user can submit a transaction for them to be merged into one CDP. Upon merging, all but one of the CDPs requested to be merged are closed, and their debt and collateral are transferred into a single CDP.

A CDP has the following states:

- **Open** – A CDP that is fully collateralized, with its CR value above the iAsset's MCR. Open CDPs remain fully usable by their owners.
- **Insolvent** – A CDP that is undercollateralized, with its CR value below the iAsset's MCR. Insolvent CDPs remain fully usable by their owners but eligible to be frozen by any user.
- **Frozen** – A CDP that has been confiscated by the protocol and no longer has an owner. A CDP becomes frozen after a user successfully submits a request against an insolvent CDP. Frozen CDPs cannot be used by their former owners.
- **Closed** – A CDP whose CR value is zero, no longer having any collateral or debt. A CDP is closed after all its debt is repaid and its collateral is withdrawn.

2.4.3 CDP Liquid Staking

Indigo supports liquid staking of ADA collateral within CDPs, allowing users to continue earning ADA rewards from the Cardano network on top of utilizing the benefits of iAsset minting. This improves capital efficiency and doubles reward capabilities – rewards earned from Cardano, and rewards earned from Indigo. Liquid staking is a unique capability offered by Indigo and will help attract liquidity from outside of the Cardano ecosystem to encourage more participation, bringing iAssets to a wider audience.

To use liquid staking, users must first have their Cardano wallet staked to their preferred stake pool⁶. The Indigo Web App automatically attaches the user's staking key when creating a CDP. All ADA deposited into that CDP will continue to earn staking rewards from the user's chosen stake pool, accruing in the user's wallet.

If the user delegates their wallet to a new stake pool after creating the CDP, the CDP will automatically earn rewards from the new stake pool.

⁶Indigo supports any [Cardano stake pool](#). A stake pool is a Cardano network node that forms the basis for consensus on the blockchain. Users can [delegate their ADA](#) to stake pools to earn ADA rewards from the Cardano network.

2.5 INDY

The Indigo DAO Token (“INDY”) is a Cardano native asset that can be owned, held, or transferred by any user. INDY serves as Indigo’s utility token, with one of its key purposes being to allow on-chain voting on DAO proposals (a “proposal”)⁷. The total supply of INDY is 35M with a 6 decimal precision. INDY’s monetary policy disallows future minting and burning, therefore making the total supply constant and unchanging. Indigo is undergoing a [Fair Launch](#), therefore there has been no pre-sale nor private distribution to investors prior to launch.

INDY will be distributed every Cardano epoch (five days), over a period of five years. There will be three distribution schedules for the community:

- **Governance Distribution** – Users who opt to stake their INDY into Indigo and participate in [DAO Governance](#) by voting on proposals will be eligible for INDY rewards proportionally to their pro-rata share of staked INDY.
- **Stability Pool Distribution** – Users who stake their iAssets in [Stability Pools](#) to ensure the protocol’s solvency will be eligible for INDY rewards proportionally to their pro-rata share of staked iAssets.
- **Liquidity Distribution** – Users who provide [liquidity](#) in DEXes and stake their LP tokens in Indigo will be eligible for INDY rewards proportionally to their pro-rata share of staked LP tokens.

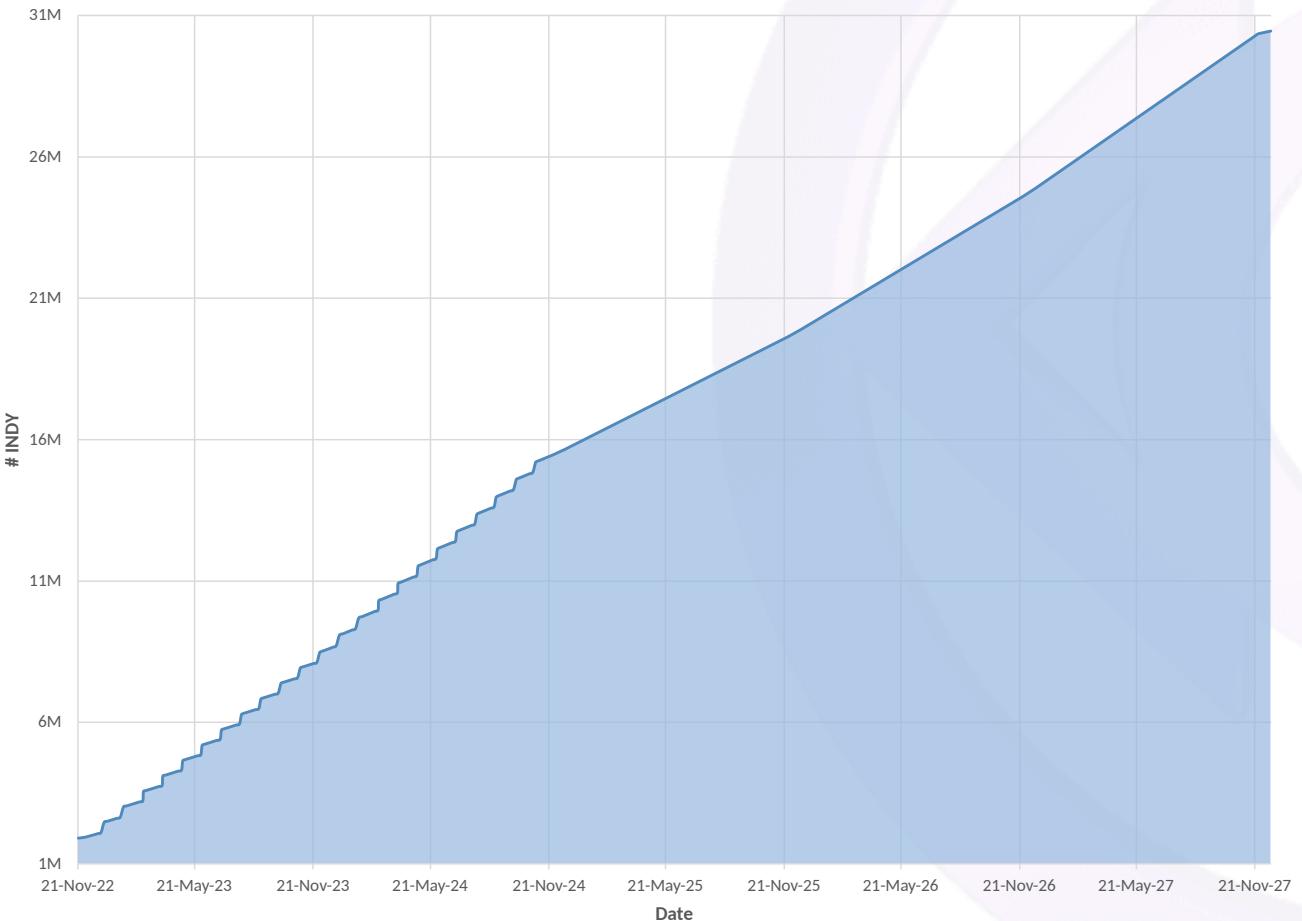

Figure 1: Distribution of INDY over five years

⁷The usage of INDY and the process of voting is described further in the [Indigo DAO Constitution and Voting Procedures](#).

2.5.1 Fair Launch

Indigo has approached its tokenomics and launch from a new perspective, with a focus on gaining community trust first, allowing the protocol to be built with a vision of fairness. Early supporters of Indigo will be among the first receivers of INDY for use within the protocol. INDY will be distributed predominantly to users of the project, rather than investors or special insiders.

After being in development for almost two years without investor funding, the initial Core Contributors of Indigo who have built the codebase – and will continue to improve, optimize, and develop new features – will receive tokens vested over two years beginning the day of mainnet launch.

Indigo has not minted, sold, allocated, distributed, or promised any tokens to third parties. The purpose of INDY is to be used within the protocol; until the launch of mainnet, there is or has been no use for INDY to be distributed or sold. Indigo's Fair Launch has helped alleviate community concerns over rug-pulling or the team not delivering a useful and highly functional product. No purchasing of tokens will be possible until the community has an opportunity to see and use Indigo for themselves.

Indigo's Fair Launch is a novel approach to bootstrapping liquidity, allowing the Indigo community to become highly collaborative, driven, and vibrant. This is evidenced by the Indigo DAO Kickstart – an effort to decentralize the launch of Indigo – which has received wide praise. This approach bolsters Indigo's core tenet of decentralization, making the launch itself a decentralized decision involving possibly thousands of individuals from around the world. Indigo will be governed by the community immediately upon launch. There will be no barriers for use. Anyone, regardless of traits, will be able to gain benefit from Indigo's iAssets. Indigo has established a new framework to allow for community-led projects to come to life, which will be used to generate INDY in as fair of a manner as possible.

2.5.2 Token Generation Event

Indigo's Token Generation Event (the "TGE") will occur upon the beginning of, and at no point prior to, deployment of the Indigo Protocol to mainnet (which is currently anticipated to be November 20th, 2022). Upon minting of INDY, the Initial Token Distribution (the "ITD") will be as follows:

- 350,000 INDY to two or three DEXs approved by the Indigo community
- 350,000 INDY to participants within the Indigo community
- 21,000,000 INDY to one or more wallets (administered by Indigo Laboratories, Inc. at the direction of the Indigo Foundation on behalf of the [Indigo DAO](#)) to be used for the sole purpose of community rewards distributions ([Stability Pools](#), [Liquidity](#), and [Governance](#))
- 4,550,000 INDY to the [DAO Treasury Reserve](#)
- 8,750,000 INDY will be allocated to Indigo Laboratories, Inc. for future building, administering, and further developing the protocol, with 7,875,000 being distributed to team members under a two-year monthly vesting schedule

At launch, the circulating supply of INDY⁸ will be 1,903,125; 350,000 of which being allocated to Cardano DEXs via an Initial Liquidity Event.

2.5.3 Initial Liquidity Event

Indigo's Initial Liquidity Event (the "ILE") will distribute and make INDY publicly available. The ILE will consist of three phases in conjunction with the launch of Indigo:

1. Airdrop
2. Liquidity Bootstrapping Event (the "LBE")
3. Liquidity Pool Creation

⁸A full detailed spreadsheet of the distribution of INDY with specific dates and allocations can be found in the open source [indy-tokenomics](#) project.

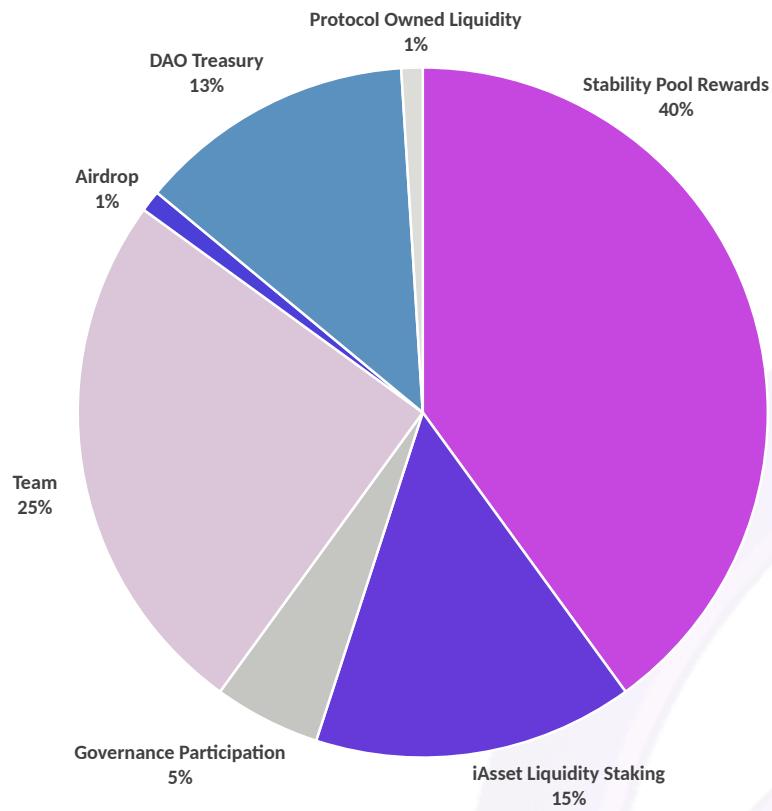

Figure 2: Allocation of INDY

Indigo Airdrop Indigo's airdrop will distribute 350,000 INDY to participants within the Indigo community. The airdrop will consist of two phases:

1. Distribution to early participants of the Indigo community
2. Distribution to stakers supporting the decentralization of Cardano and Indigo

Each phase will be distributed 175,000 INDY. Cardano wallet addresses have been collected by Indigo Laboratories, Inc. (the “Labs”) and will be forwarded to Vending Machine.⁹ The Labs will send 350,000 INDY to Vending Machine, who will subsequently distribute INDY to qualified recipients via the Indigo Web App.

To redeem airdropped INDY, qualified users will need to connect their wallet to the Indigo Web App and follow the in-app instructions to withdraw INDY into their wallets. Users will be able to determine whether they qualify for the airdrop upon connecting their wallets and navigating to the appropriate reward page. Users will have until March 31st 2023 to withdraw their INDY rewards into their wallets. Any INDY not withdrawn by this time will not be eligible to be withdrawn by users and instead will be subject to redistribution by the Labs.

Members or affiliates of the Labs or Indigo Foundation make no promises on the distribution of tokens. No action or series of actions guarantees a user to receive INDY.

Airdrop 1: Distribution to Early Participants Qualified participants for Airdrop 1 fit into either one of two categories:

1. Participants who showed their interest by successfully completing each of the processes, which were:
 - (a) Participate in Indigo's [first temperature check](#) in the Indigo Forum
 - (b) Connect their Indigo Forum account with their Discord account
 - (c) Complete the [Indigo Quiz](#) to become an Indigo Guru
2. Participants who aided the Indigo community, as identified by the Labs' team

172,751.924982 INDY is to be distributed to wallets that fit into the first category, and 2,248.07304 INDY is to be distributed to wallets that fit into the second category. A total of 3,458 wallets qualified for the first category, and 30 wallets qualified for the second category.

Addresses deemed to be suspicious or fraudulent were removed from the first category.

⁹Vending Machine is a Cardano token distribution system.

Airdrop 2: Distribution to Decentralization Stakers 175,000 INDY will be distributed as a reward to users who helped boost decentralization of the Cardano network by staking with a member of the [Cardano Single Pool Alliance](#) (CSPA). To have qualified for receiving this reward, a user had to have been staking a minimum of 10 ADA in one of 357 pools on November 6th, 2022. A total of 79,679 wallets qualified to be eligible to withdraw rewards. Each user who connects a qualified wallet to the Indigo Web App will be eligible for a one-time withdrawal of 5 INDY on a first come first serve basis.

Indigo Liquidity Bootstrapping Event and Liquidity Pool Creation In partnership with [Minswap](#), Indigo will begin a Liquidity Bootstrapping Event (the “LBE”) on November 14th 2022¹⁰. The goal of the LBE is to use a decentralized and transparent process to discover a fair price for INDY. After the LBE starts, users can deposit ADA into the Minswap Launch Bowl. Deposited ADA will be used to create INDY/ADA Liquidity Pools (a “LP”).

The Minswap LP will consist of 75% of deposited ADA in the LBE paired with 262,500 INDY. Depending on slippage analysis at the time of the LBE end date of November 20th 2022, 25% of deposited ADA in the LBE paired with 87,500 INDY will be used to create LPs on either one or two DEXs approved by the Indigo community.

2.6 Stability Pools

A Stability Pool (a “SP”) helps maintain iAsset solvency by acting as the source of liquidity to repay debt from liquidated CDPs, thus intending all minted iAsset supply to remain overcollateralized.

Every supported iAsset has its own SP (e.g., iBTC SP, iETH SP). A user can deposit corresponding iAsset into a SP to become a SP staker (a “SP staker”). SP stakers provide stability to the protocol by offering their iAssets to be used for liquidations.

SP Liquidation (“SPL”) is the process of utilizing a SP to liquidate a CDP, where iAsset deposited in a SP are burned to repay the debt of an undercollateralized CDP. In exchange, SP stakers earn a share of the collateral that was confiscated from liquidated CDPs. When CR falls below the iAsset MCR, the CDP is considered insolvent and subject to liquidation, which amounts to canceling the debt where:

1. the same amount of iAsset debited by the CDP is burned from the corresponding SP; and
2. the collateral from the CDP is proportionally distributed to SP stakers.

As CDPs become liquidated, SP stakers lose a pro-rata share of their iAsset deposits while gaining a pro-rata share of the liquidated collateral. An incentive for SP stakers to participate in SPL is the possibility of earning net gains from liquidations. Under normal circumstances, the value of the collateral earned may be greater than the value of the canceled debt, because a liquidated CDP is likely to have a CR value above 100% (the value of the iAsset).

SPL first requires that CDPs are frozen. Each liquidation request of a CDP is executed against its iAsset’s associated single SP. Optionally, users can make requests for CDPs to be merged. As illustrated in the [CDP merge figure](#), three CDPs could be merged into a single CDP. The resulting merged CDP can then be liquidated against the SP. While only a single liquidation can occur per SP at once, multiple CDPs can be merged in parallel. Merging CDPs effectively enables multiple frozen CDPs to be liquidated simultaneously.

Indigo allows for both full and partial liquidations. A full liquidation, as illustrated in the [SPL figure](#), repays all debt of a CDP and closes the CDP. A partial liquidation, as illustrated in the [partial SPL figure](#), repays some debt of a CDP and keeps the remaining position frozen. If a CDP debt is higher than the entire amount of iAssets in the related SP, the protocol attempts to cancel as much debt as possible with the iAsset supply available. Any remaining non-liquidated collateral and debt of the CDP remains frozen until more iAsset is deposited into the SP and another liquidation is initiated.

¹⁰More information about Indigo’s LBE will be available on [Indigo’s Medium](#).

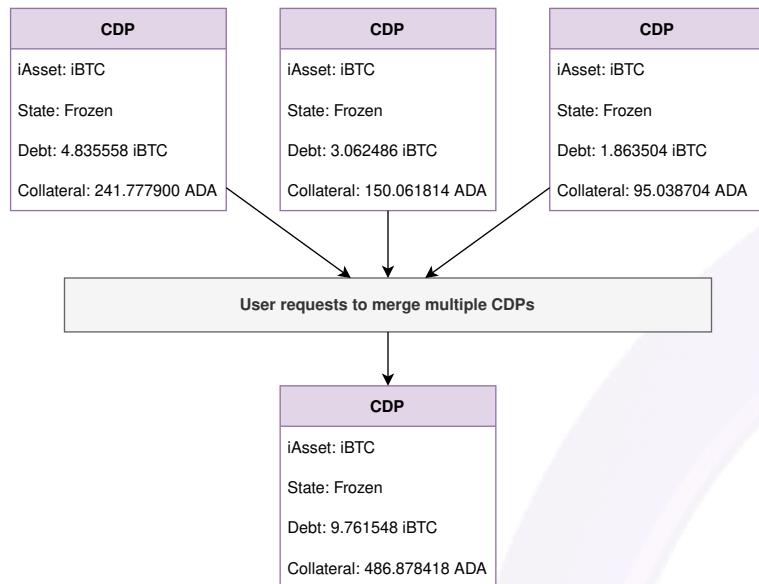

Figure 3: Three CDPs being merged into one

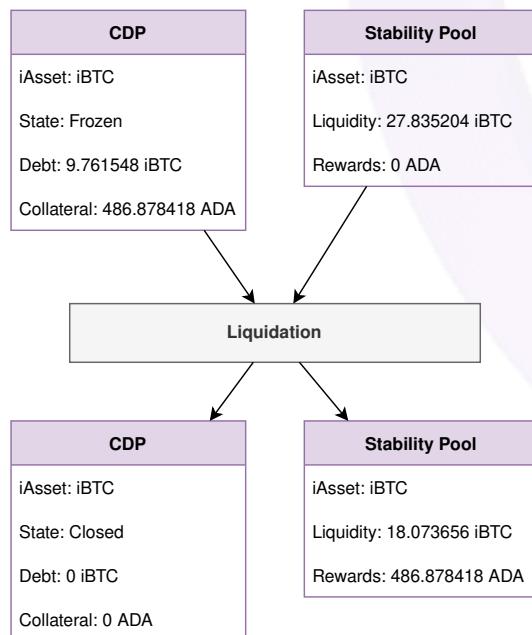

Figure 4: Illustration of a full liquidation where sufficient funds are present in the SP

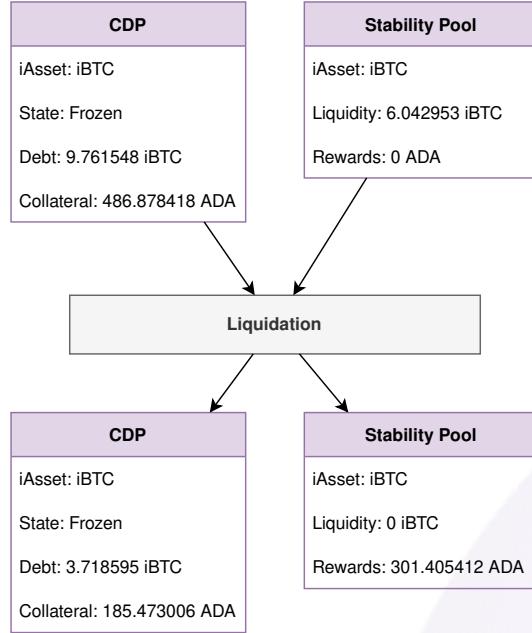

Figure 5: Illustration of a partial liquidation where there are insufficient funds present in the SP

Values for the liquidated CDP and associated SP can be calculated using:

$$\begin{aligned}
 w &= a - \min \{a, b\} \\
 x &= d - \min \{a, e\} \frac{d}{a} \\
 y &= e - \min \{a, e\} \\
 z &= g + \min \{a, e\} \frac{d}{a}
 \end{aligned}$$

Where:

- w is the updated debt of the CDP after liquidation
- x is the updated amount of collateral in the CDP after liquidation
- y is the updated amount of iAsset in the SP after liquidation
- z is the updated amount of ADA rewarded to the SP after liquidation
- a is the amount of debt of the CDP before liquidation
- b is the amount of iAsset in the SP
- d is the amount of collateral in the CDP before liquidation
- e is the amount of iAsset in the SP before liquidation
- g is the amount of ADA rewarded to the SP before liquidation

2.6.1 Stability Pool Staking Fees

Users can stake and unstake iAssets from SPs at any time. To stake iAsset, a user needs to create a SP account by depositing 7 ADA and the amount of iAsset they desire to stake. 2 ADA is returnable to the user upon closing the SP account, which involves withdrawing all their iAsset and earned rewards. 5 ADA is taken as a fee. Users pay a 1 ADA fee for each new iAsset deposit into their SP account.

SP fees are collected and distributed to all SP stakers as part of liquidation rewards.

2.6.2 Stability Pool Liquidation Rewards

As liquidations occur, SP stakers lose a pro-rata share of iAsset deposits and gain a pro-rata share of ADA rewards. A SP “product constant” maintains mathematical state of liquidations occurred. When a SP is first created, its product constant is set to one. Upon liquidation, the product constant can be calculated using the formula:

$$c = a \left(1 - \frac{b}{d}\right)$$

Where:

- c is the new product constant
- a is the current product constant
- b is the amount of iAsset debited from the SP for the liquidation
- d is the total amount of iAsset in the SP

A SP “compounded constant” maintains the mathematical state of rewards earned from liquidations relative to the product constant. When a SP is first created, its compounded constant is zero. Upon liquidation, the compounded constant can be calculated using the formula:

$$r = a + \frac{bc}{d}$$

Where:

- r is the new compounded constant
- a is the current compounded constant
- b is the amount of ADA earned during the liquidation
- c is the product constant before the liquidation
- d is the total amount of iAsset in the SP before the liquidation

When an action is taken against a SP, such as a deposit of an iAsset or a liquidation, its state is updated. The SP state data structure – represented in the [SP state table](#) – is stored within the UTXO of the SP; “iAsset Deposit” records the number of iAsset in the SP deposited by all users.

A SP epoch ends when all iAsset from a SP is drained via liquidations. Epoch is a running tally of the number of occurrences there have been when the SP’s total iAsset deposit reached zero. Upon updating the SP state, if the total iAsset in the SP is to be set to zero, then this marks the end of an epoch. At the end of an epoch, the following occurs:

- Epoch is recorded in a UTXO paired with the compounded constant value after the latest liquidation
- The SP state is updated with the values:
 - epoch incremented by one;
 - product constant set to one; and
 - compounded constant set to zero.

Table 2: State stored upon updates to a SP

Name	Description
Product Constant	The new product constant (c)
Compounded Constant	The new compounded reward (r)
iAsset Deposit	The updated amount of iAsset deposited into the SP
Epoch	The current epoch

When a user deposits iAsset into a SP, a SP staker “account record” is created or updated for that user’s account. The account record is represented the same as SP state and stored within the UTXO of the SP staker’s position; iAsset Deposit records the number of iAssets owned individually by the SP staker. All other values for the account record are copied from the SP state.

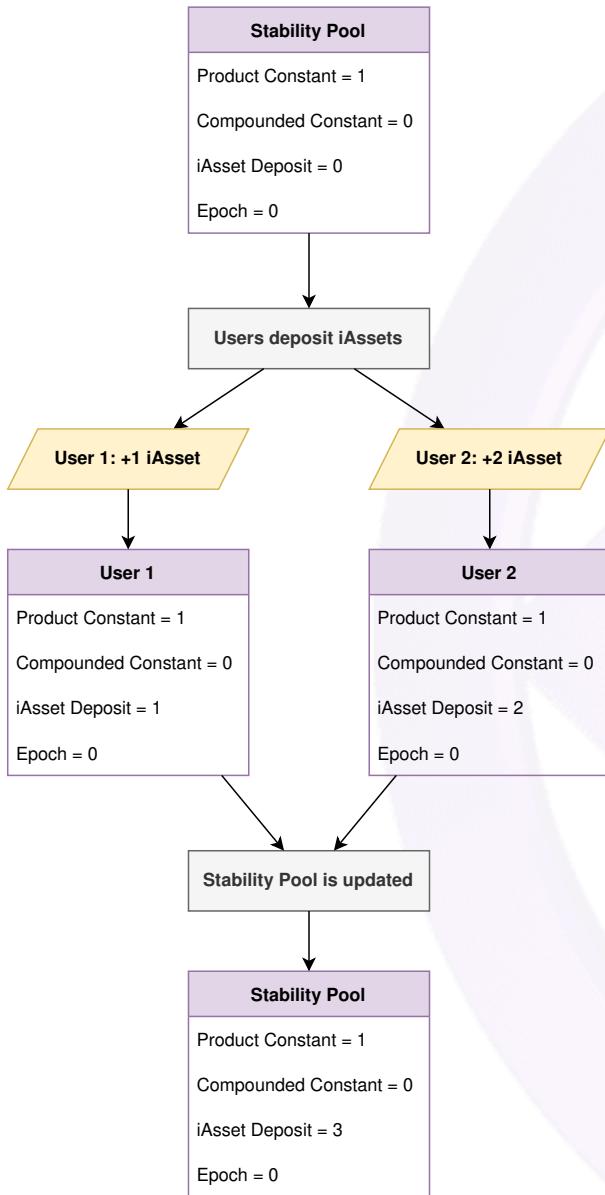

Figure 6: iAsset being deposited into a new SP

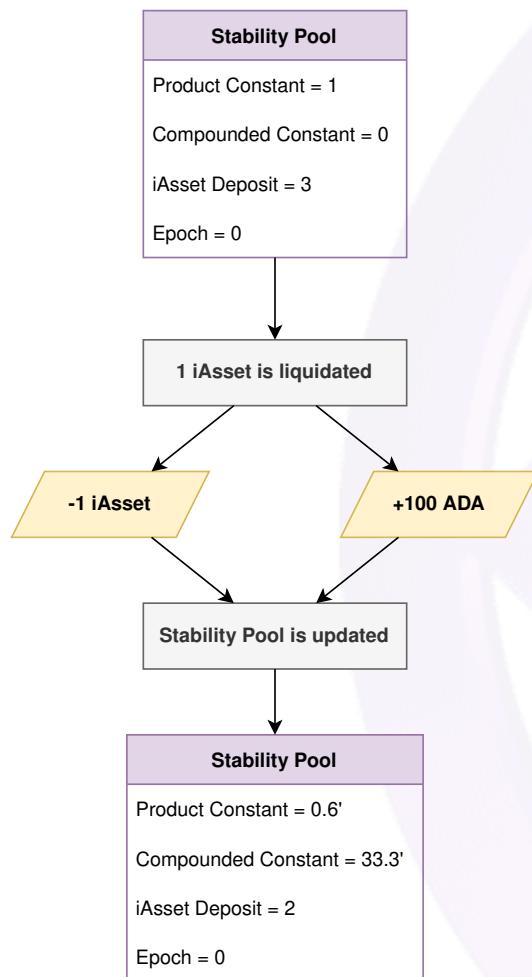

Figure 7: SP state being updated after a liquidation occurs

During a liquidation, iAsset is extracted from a SP. Proportionally, the ownership share of the iAsset within each SP staker's position is reduced. If the epoch in the account record matches the epoch in the SP state, the amount of iAsset an individual SP staker holds can be calculated using:

$$m = a \frac{c}{b}$$

Where:

- m is the amount of iAsset owed to the SP staker
- a is the amount of iAsset the SP staker deposited (retrieved from the account record)
- c is the current product constant (retrieved from the SP state)
- b is the product constant when the SP staker deposited their iAsset (retrieved from the account record)

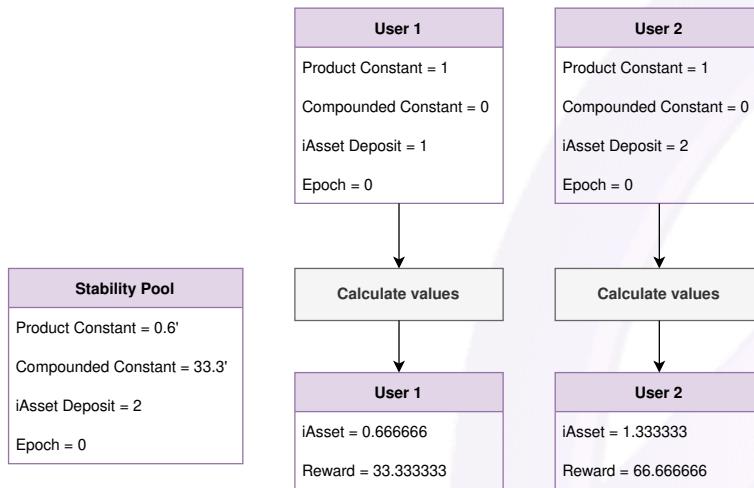

Figure 8: SP staker rewards after a liquidation has occurred

If the epoch in the account record does not match the epoch in the SP state, then the amount of iAsset owned to the SP staker (m) is zero. This is due to all the user's iAsset having been burned during a previous epoch.

During a liquidation, an ADA reward is deposited into the SP. Proportionally, the share of ADA rewards each SP staker is owed increases. The formula to calculate how much ADA an individual SP staker is rewarded from the SP is:

$$l = a \frac{r - d}{b}$$

Where:

- l is the amount of ADA owed to the SP staker
- a is the amount of iAsset the SP staker deposited (retrieved from the account record)
- r is the current compounded constant (retrieved from the SP state or recorded compounded constant for the matching epoch)
- d is the compounded constant when the SP staker deposited their iAsset (retrieved from the account record)
- b is the product constant when the SP staker deposited their iAsset (retrieved from the account record)

If an account record's epoch does not match the epoch of the SP state, then r is set to the latest recorded compounded constant for the epoch. This is due to the compounding constant resetting to zero after an epoch ends, therefore all SP staker positions during that epoch would be closed because all their iAsset would have been utilized during liquidations.

When a SP staker modifies their position, either by depositing or withdrawing iAsset or ADA reward, then their previous position is considered closed, and a new position is created. If a user withdraws all their iAsset, then a new position is not opened. The SP state is also updated to reflect the new deposit or withdrawal, i.e., the iAsset Deposit is updated by the amount of iAsset deposited or withdrawn.

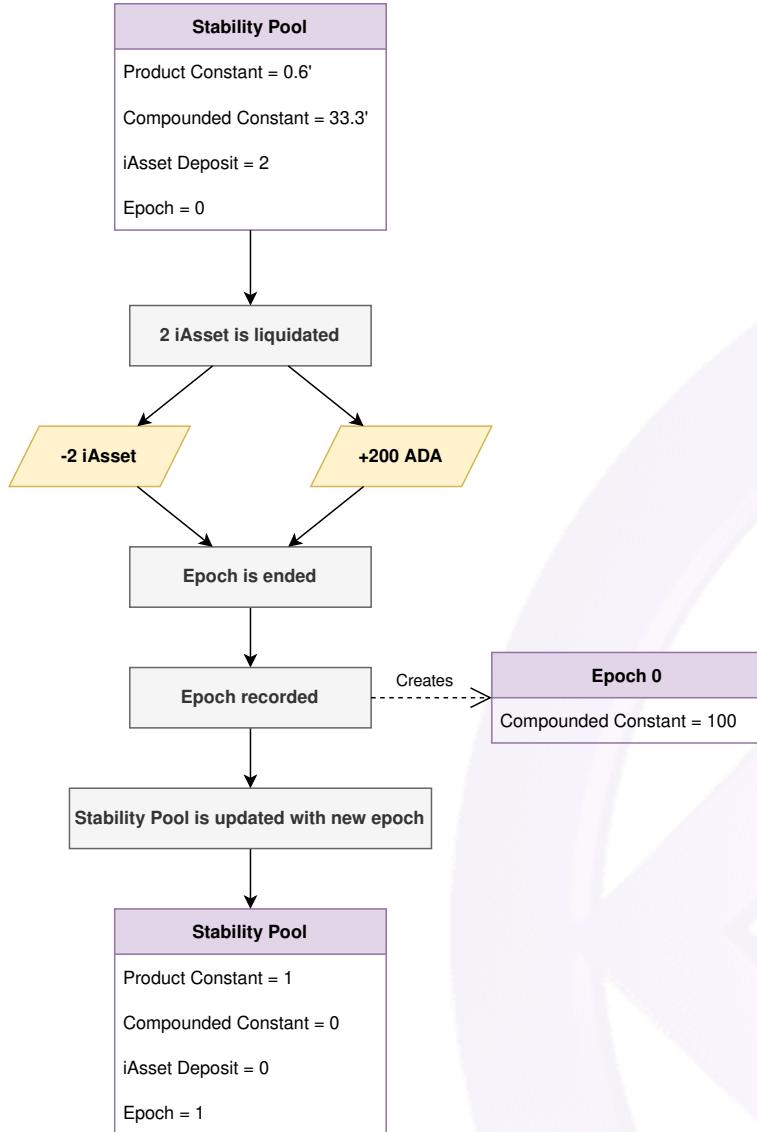

Figure 9: Illustration of a new SP epoch beginning after a liquidation drains all iAsset

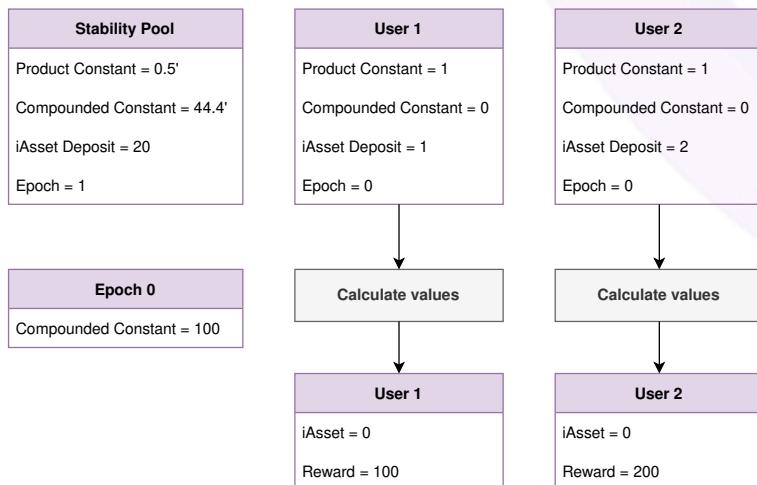

Figure 10: SP staker rewards after SP has been drained and a new epoch has begun

2.6.3 Stability Pool Staking Rewards

SP stakers contribute to maintaining the solvency of the protocol and the iAsset pegs. In return for staking their iAsset, Indigo offers rewards in the form of ADA from liquidated CDPs and INDY.

INDY is rewarded each Cardano epoch (every five days) and determined by the market cap of the iAsset as well as how much iAsset is being staked relative to other iAssets. The less iAsset that is staked in a SP relative to the total number of iAsset minted, the higher the INDY reward; the more iAsset that's staked, the less the INDY reward.

Calculating SP INDY rewards is broken into two phases:

1. Calculation of how much INDY is rewarded per SP
2. Calculation of SP staker's share of the SP's reward

Table 3: Distribution schedule of INDY unlocked every epoch for Stability rewards

Beginning From	# INDY per Epoch
1-Dec-22	28,768
1-Dec-23	33,562
26-Sep-24	33,561
30-Nov-24	38,356
30-Nov-25	43,150
30-Nov-26	47,945

Calculating INDY rewarded per SP is based on three variables:

1. Standard deviation of the SP's iAsset's underlying asset (σ)
2. Stability Pool Saturation (φ)
3. Market cap of the SP's iAsset (ω)

Standard deviation for a SP (σ) can be calculated using the formula:

$$\sigma = \begin{cases} \sqrt{\frac{\sum_{i=1}^{|x|} (x_i - \bar{x})^2}{|x|}} & \text{if } |x| > 30 \\ 0 & \text{if } |x| \leq 30 \end{cases}$$

Where:

- σ is the SP's standard deviation
- x is the set of the iAsset's tracked asset's historical daily close price for the past year (or maximum amount of time that data exists for)

Stability Pool Saturation (φ) can be calculated by taking the SP's deposits and dividing by the iAsset's total supply:

$$\varphi = \begin{cases} \frac{\sum_{i=1}^{|a|} a_i}{b} & \text{if } c \geq d + 6 \\ 0 & \text{if } c < d + 6 \end{cases}$$

Where:

- φ is the SP's saturation
- a is the collection of iAsset deposits in the SP
- b is the total supply of the iAsset
- c is the current epoch number
- d is the epoch number the iAsset was launched during

Market cap (ω) can be calculated by taking the total number of the SP's iAsset minted and multiplying by the price of the iAsset's tracked asset's price:

$$\omega = \begin{cases} ab & \text{if } c \geq d + 6 \\ 0 & \text{if } c < d + 6 \end{cases}$$

Where:

- ω is the SP's iAsset market cap
- a is the total number of iAsset that have been minted
- b is the price of the iAsset's tracked asset
- c is the current epoch number
- d is the epoch number the iAsset was launched during

The amount of INDY to be distributed to a SP is calculated based on a value of ρ , representing an average of σ , φ , and ω , and is calculated daily using:

$$\rho = \begin{cases} \frac{\frac{1/\sigma}{\sum_{i=1}^{|a|} \begin{cases} 1/a_i & \text{if } a_i > 0 \\ 0 & \text{if } a_i = 0 \end{cases}} + \frac{1/\varphi}{\sum_{i=1}^{|b|} \begin{cases} 1/b_i & \text{if } b_i > 0 \\ 0 & \text{if } b_i = 0 \end{cases}} + \frac{\omega}{\sum_{i=1}^{|c|} c_i}}{3} & \text{if } \sigma > 0 \text{ and } \varphi > 0 \text{ and } \omega > 0 \\ \frac{1/\sigma}{\sum_{i=1}^{|a|} \begin{cases} 1/a_i & \text{if } a_i > 0 \\ 0 & \text{if } a_i = 0 \end{cases}} & \text{if } \sigma > 0 \text{ and } \varphi = 0 \text{ and } \omega = 0 \\ 0 & \text{otherwise} \end{cases}$$

Where:

- ρ is the distribution value for the SP
- a is the collection of each SP's σ
- b is the collection of each SP's φ
- c is the collection of each SP's ω
- σ is the SP's standard deviation
- φ is the SP's saturation
- ω is the SP's iAsset market cap

The amount of INDY to distribute to each SP can be calculated based off each SP's daily calculated ρ :

$$a = \rho \frac{c}{5}$$

Where:

- a is the amount of INDY to distribute to the SP for a particular day within the epoch
- ρ is the distribution value for the SP for a particular day within the epoch
- c is the amount of INDY being distributed to all SPs for the epoch

Calculating INDY reward per SP staker is based on the a for the user's SP and the amount of time the user was staked in the SP:

$$k = \begin{cases} a & \frac{b}{\sum_{i=1}^{|c|} c_i} \text{ if } e \geq 24 \\ \sum_{i=1}^{|c|} \begin{cases} c_i & \text{if } d_i \geq 24 \\ 0 & \text{if } d_i < 24 \end{cases} & \text{if } e < 24 \end{cases}$$

Where:

- k is the amount of INDY to distribute to the SP staker for a particular day during the epoch
- a is the amount of INDY to distribute to the SP for a particular day within the epoch
- b is the total amount of iAsset staked by the SP staker
- c is the collection of iAsset amounts staked by all SP stakers
- d is the collection of hours all SP stakers have been staking iAsset for
- e is the total hours the LP staker has been staking their LP tokens for

Total amount of INDY to distribute to the SP staker is calculated by summing all the k values calculated during each day of the epoch:

$$a = \begin{cases} \sum_{i=1}^5 b_i & \text{if } c \geq 24 \\ 0 & \text{if } c < 24 \end{cases}$$

Where:

- a is the amount of INDY to distribute to the SP staker for the epoch
- b is the collection of k values calculated each day of the epoch
- c is the total hours the SP stakers has been staking iAsset for

SP stakers can withdraw their accumulated INDY staking rewards (the sum of a for each epoch they're owed rewards) via the Indigo Web App. Unclaimed rewards are withdrawable for three months. Any rewards not claimed within three months after being rewarded are redistributed to Members via the [Collector](#).

2.7 Oracles

To determine the value of collateral held within CDPs and the intended prices of iAssets, Indigo makes use of Oracles¹¹ available on Cardano. An Oracle queries external data sources for information and makes that information available on-chain.

Indigo is designed to be Oracle agnostic, meaning that it can support any Oracle that publishes data on the Cardano blockchain so long as the data format conforms with the protocol's specifications defined in the [CDP](#) section.

2.8 Liquidity Staking Rewards

A benefit of iAsset composability is that they can be provided as liquidity to any Decentralized Exchange (a "DEX"). Having iAssets available on several DEXs is a key factor to promote Indigo's integration into the broader ecosystem, allowing other users to obtain and use iAssets without having to manage a CDP.

Users who provide liquidity to DEXs receive tokens proving they have deposited iAssets (a "LP token"). Indigo rewards users who provide iAsset liquidity by allowing them to stake their LP tokens in the protocol and receive INDY rewards.

¹¹Oracles provide a way for decentralized blockchain applications to access existing data sources.

Stakers of LP tokens can unstake their tokens at any time. Members can vote on whitelisting a specific LP token to be eligible for staking rewards. Only double-sided LP tokens representing one iAsset and one non-iAsset token in equal proportions are allowable and eligible for rewards (e.g., iBTC/ADA LP token).

Table 4: Distribution schedule of INDY unlocked every epoch for Liquidity rewards

Beginning From	# INDY per Epoch
21-Dec-22	4,795
21-Dec-23	9,590
11-Oct-24	9,589
20-Dec-24	14,383
20-Dec-25	19,178
20-Dec-26	23,972

INDY is rewarded to LP stakers each epoch and determined by the market cap of the iAsset as well as how much representative iAsset is being staked relative to other iAssets. The less representative iAsset that is staked in whitelisted LP tokens relative to the total number of iAsset minted, the higher the INDY reward; the more representative iAsset that's staked the less the INDY reward.

Calculating Liquidity rewards is broken into two phases:

1. Calculation of how many INDY is rewarded per iAsset
2. Calculation of LP staker's share of the iAsset reward

Calculating liquidity saturation (φ) requires taking the representative iAsset staked divided by the iAsset total supply:

$$\varphi = \frac{\sum a}{b}$$

Where:

- φ is the liquidity saturation
- a is the set of total iAsset staked for each pool corresponding with the set of whitelisted LP tokens for the iAsset
- b is the total supply of the iAsset

Calculating INDY rewarded per iAsset for a day during an epoch is based on assessing the liquidity saturation comparative other iAssets in addition to the iAsset market caps:

$$k = \begin{cases} \frac{a}{5|b|} & \text{if } \varphi \geq 0.2 \text{ and } \varphi \leq 0.3 \\ \left(\begin{array}{l} \text{let } l = \sum_{i=0}^{|b|} \begin{cases} \frac{a}{5|b|} & \text{if } b_i \geq 0.2 \text{ and } b_i \leq 0.3 \\ 0 & \text{otherwise} \end{cases} \\ \text{let } m = \frac{1/\varphi}{\sum_{i=1}^{|b|} \begin{cases} 0 & \text{if } b_i \geq 0.2 \text{ and } b_i \leq 0.3 \\ 1/b_i & \text{otherwise} \end{cases}} \\ \text{let } o = \frac{cd}{\sum_{i=1}^{|b|} \begin{cases} 0 & \text{if } b_i \geq 0.2 \text{ and } b_i \leq 0.3 \\ x_i y_i & \text{otherwise} \end{cases}} \\ (\frac{a}{5} - l)(m + o) \end{array} \right) & \text{otherwise} \end{cases}$$

Where:

- k is the amount of INDY to distribute to the iAsset's LP stakers for a particular day within the epoch
- a is the amount of INDY being distributed to all LP stakers for the epoch
- b is the collection of each iAsset's φ
- c is the intended price of the iAsset
- d is the total supply of the iAsset
- x is the collection of intended iAsset prices of the corresponding collection b
- y is the collection of total iAsset supplies of the corresponding collection b

INDY to distribute to an individual LP staker is calculated based on the staker's share of total iAsset staked:

$$r = k \frac{xy/z}{b \sum_{i=1}^{|a|} a_i b_i / c_i}$$

Where:

- r is the amount of INDY rewarded to the LP staker for a particular day within the epoch
- k is the amount of INDY to distribute to the iAsset's LP stakers for a particular day within the epoch
- a is the collection of staked amounts of LP tokens
- b is the collection of total iAsset staked for pools corresponding with the LP tokens in collection a
- c is the collection of total supply of the corresponding LP tokens collection a
- x is the LP staker's amount LP tokens staked
- y is the total iAsset staked in the LP staker's associated pool
- z is the total supply of the LP tokens for the LP staker's associated pool

r is calculated daily for each user, and the sum of all r values for each day is the amount of INDY the user is rewarded for the epoch:

$$a = \sum_{i=1}^5 b_i$$

Where:

- a is the amount of INDY rewarded to the LP staker the epoch
- b is the collection of r values calculated for each day within the epoch

LP stakers can withdraw their accumulated INDY staking rewards (the sum of a for each epoch they're owed rewards) via the Indigo Web App. Unclaimed rewards are withdrawable for three months. Any rewards not claimed within three months after being rewarded are redistributed to Members via the [Collector](#).

2.9 iAsset Price Stability

[iAssets are pegged to tracked assets](#). To maintain price pegs, Indigo relies on protocol rules to incentivize arbitrageurs and market forces to stabilize prices. These rules ensure that iAssets are always fully collateralized, giving further confidence to users that iAsset prices will match their counterparts.

Periodically, Indigo receives price data from the outside world via [Oracles](#). The rate at which price feeds are updated is configurable, and at launch will be set to once per hour. After price is updated, CRs are adjusted across the protocol, allowing for liquidations to occur for CDPs whose CR falls below the iAsset's MCR.

If an iAsset drops in price relative to its peg, it provides CDP owners an opportunity to buy the iAsset to repay their loan at a discount. This can cause buying pressure on the iAsset to rise its price. If there is an abundance of iAsset supply, Indigo can increase MCR towards the iAsset mode CR.

Each CDP has its own CR. The iAsset mode CR represents the most frequent CR value users select for their CDPs. By moving MCR towards the mode CR, probability of liquidation increases, incentivizing users to close their CDPs, which can cause iAsset buying pressure and reduced iAsset supply.

A higher MCR results in a higher cost to mint iAsset supply, reduces the maximum leverage utilizable, and increases the margin of arbitrage value for Stability Pool stakers. This creates a disincentive to create new iAsset supply and incentivizes users to buy existing iAsset supply to stake into the Stability Pool. The reduction of supply paired with the increased buying pressure can push the iAsset price upwards.

When an iAsset is first launched, its supply is zero, yet its demand may be high because users desire to purchase it. This causes an immediate supply and demand imbalance, potentially causing the iAsset to trade higher than its intended peg.

A low MCR reduces the cost of minting iAsset supply and maximizes the leverage utilizable. This creates an incentive for users to create new iAsset supply, hence is why Indigo's iAssets will initially be launched with a MCR of 110%. An iAsset MCR of 110% forces the price of the iAsset to be no more than 10% above its peg by creating an arbitrage opportunity. Users at any time can mint iAsset at a cost of 10% higher than the iAsset's pegged price, allowing iAsset to be immediately sold if the market premium is higher than 10%. iAsset trading above its peg also offers an opportunity to borrow at a lower cost, further incentivizing more supply to be minted and possibly creating additional sell pressure if users choose to take advantage of the leverage.

If there is an abundance of iAsset demand and limited supply, Indigo can decrease MCR towards 100%. This in turn reduces the cost of minting iAsset, pushing the price of the iAsset down. Indigo's quick liquidation mechanism via [Stability Pools](#) allows for high capital efficiency and support for very low collateralization while still providing incentive for users to participate in arbitrage. MCR value setting considers the average CR of iAssets, ensuring that iAssets are always overcollateralized irrespective of any market conditions or possible future events.

2.10 Governance

Governance is the decentralized voting process through which *proposals* for updating the protocol are introduced and either accepted or rejected by the community (collectively known as the “Indigo DAO”). All change to the protocol must go through governance.

Indigo has a 3-pillar structure built for long term sustainability:

1. **Indigo DAO** – Decentralized association of members governing the protocol.
2. **Indigo Foundation** – Foundation Company incorporated in the Cayman Islands for interacting with the real-world on behalf of the Indigo DAO.
3. **Indigo Laboratories, Inc.** – A Wyoming corporation contracted by the Indigo Foundation responsible for development of Indigo and blockchain technologies.

2.10.1 Indigo DAO

The Indigo DAO (the “DAO”) is an informal non-jurisdictional, non-hierarchical, and nonprofit association of fluctuating individuals and entities who are uncoordinated and act together using a token. The DAO owns and controls the Indigo Protocol. All changes to the protocol must go through governance. Governance is the decentralized voting process through which proposals for updating the protocol are introduced and either accepted or rejected by the Indigo DAO Members.

[INDY](#) serves as Indigo DAO’s utility token with one of its purposes being to allow voting on DAO proposals. Users who stake their INDY in Indigo’s governance thereby become a DAO Member (a “Member”) and can vote on proposals.

Members who wish to assist in managing the administrative and technical operations of Indigo (e.g.: organizing meetings of Members, submitting governance Proposals, or leading Working Groups) can be elected by other Members and become Core Contributors.

2.10.2 Indigo Foundation

The Indigo Foundation (the “Foundation”) entity provides an extremely flexible framework that supports off-chain functions necessary for executing the intent of the Indigo DAO. While the Indigo DAO is not a legal entity, the Foundation is, and therefore can enter into legal agreements with other real-world entities. The Foundation is established to help implement approved actions of the DAO that cannot otherwise be implemented in an automated or computational manner. The Foundation can engage with governmental authorities (for tax, regulatory, or other purposes), contract with vendors, and educate the community about Indigo – all as directed by the DAO.

The Foundation's authority is limited to implementing the votes of the DAO and otherwise supporting Indigo. The DAO may vote to amend the responsibilities of the Foundation at any time. The Foundation does not have possession of or control of any Indigo or user funds. The DAO is required to fund the Foundation and provide the Foundation with any tokens needed to make payments to third party vendors.

2.10.3 Governance Process

An owner of INDY who chooses to stake INDY within Indigo becomes a Member and obtains the right to vote on proposals. A vote can be either in the form of yes, indicating favor of passing the proposal, or no, indicating favor of rejecting the proposal. Each Member receives voting power weighted by their amount of INDY staked.

The Governance Process consists of three phases.

Step 1 – Temperature Check: A user creates and submits their idea to the [Indigo Forum](#). The idea will be reviewed by Moderators and Indigo Forum users for consistency with the Indigo DAO Constitution. Forum users will review and provide comments or suggested improvements to the idea, and eventually vote on it within the Forum.

Step 2 – Proposal: If a Temperature Check results in a positive outcome, a user needs to deposit INDY to submit a proposal on-chain. In addition, the user submitting the proposal should also create [voting shards](#) by depositing some ADA. Voting shards will maintain a record of votes and are meant to enhance on-chain voting performance. Members can vote on the proposal using their staked INDY. Indigo's [Adaptive Quorum Biasing](#) mechanism automatically adjusts the threshold to determine how many positive votes are required for the proposal to pass.

Step 3 – Execution: After a proposal's Voting Period ends, it moves to the execution phase. If the proposal passed, users could execute it and the proposal creator can retrieve their INDY deposit as well as their ADA deposit within each voting shard.

If the proposal fails, the proposal is closed and the proposal creator loses their INDY deposit. The INDY is instead sent to the [Treasury](#).

2.10.4 Staking

Users who stake their [INDY](#) in Indigo's governance (thereby becoming a "Member") can vote on proposals. A vote can be either in the form of *yes*, indicating favor of passing the proposal, or *no*, indicating favor of rejecting the proposal. Each INDY staker receives voting power weighted by their amount of INDY staked and must either use either all or none of their voting power.

When a Member votes on a proposal, their INDY stake is locked until that proposal's Voting Period has concluded (i.e., either approved, rejected, or expired). Locked INDY cannot be withdrawn from the protocol. If a Member votes on multiple proposals, their INDY is unlocked after the most recently created proposal they voted on concludes. If their INDY is in an unlocked state, then users can withdraw their INDY stake.

After casting a vote, it cannot be changed or undone. Voting power is set to the total amount of INDY staked at the time of casting. If a Member deposits additional INDY into their position, they can use that INDY in addition to the existing locked INDY to vote on another proposal but cannot use that additional INDY to vote on a proposal they've already voted on. If the user deposits INDY after casting a vote and before casting another vote, then the INDY can be withdrawn. After depositing INDY and casting a vote for another proposal, all deposited INDY becomes locked and cannot be withdrawn until the end of the proposal.

2.10.5 Governance Rewards

Members who participate in Governance by casting a vote at least once every ninety days (configurable itself by Member vote) are rewarded with INDY each epoch. Each epoch, INDY is unlocked and distributed to all qualifying Members. The amount of INDY each Member receives is based on the ratio of a Member's stake relative to the total amount of INDY staked, and can be calculated using:

$$a = \frac{bc}{\sum_{i=1}^{|m|} m_i}$$

Where:

- a is the amount of INDY a Member is rewarded
- b is the amount of INDY a Member has staked
- c is the amount of INDY rewarded to all Members for the epoch
- m is the collection of INDY amounts staked by all Members

Table 5: Distribution schedule of INDY unlocked every epoch for Governance rewards

Beginning From	# INDY per Epoch
6-Dec-22	2,398
6-Dec-23	3,596
5-Dec-24	4,795
13-Jul-25	4,794
5-Dec-25	5,993
5-Dec-26	7,191

2.10.6 Adaptive Quorum Biasing

A proposal is considered passed when the ratio of *yes* votes over *no* votes exceeds the quorum threshold. Indigo uses a dynamic vote-threshold mechanism called Adaptive Quorum Biasing (“AQB”) to calculate the quorum threshold value. AQB lowers the quorum threshold as more INDY is used to vote. If voter participation is low, then a high majority of those votes must be in favor of the proposal. If voter participation is high, then a lower majority of those votes must be in favor of the proposal. Always at least 50% of votes must be in favor of a proposal for it to pass.

For example, if 29% of all circulating supply of INDY is used to vote during a proposal’s Voting Period, the quorum threshold for that proposal would be set to 66%. This means that 66% or more of the total INDY used for voting would be required to vote *yes* for the proposal to be considered passed. If more than 34% of the total INDY used for voting voted *no*, then the proposal would fail.

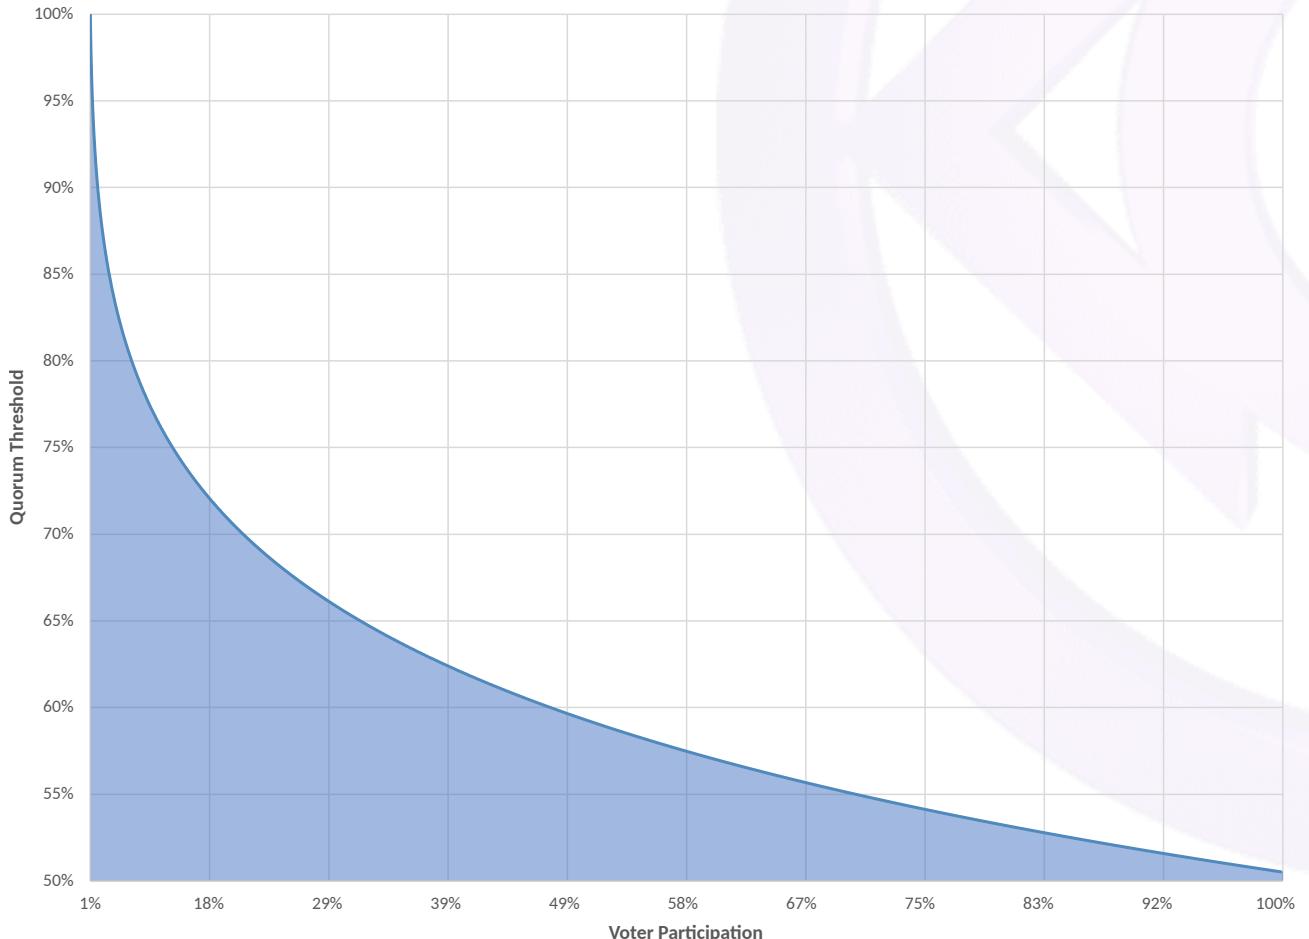

Figure 11: Illustration of quorum threshold decreasing as voter participation increases

To determine if a proposal is approved, the electorate (e) first needs to be calculated. e is INDY circulating supply at the time of a proposal's conclusion. INDY has a fixed distribution schedule, so e can be derived by taking the launch time of the protocol, the end time of the proposal, and other values related to Indigo's token distribution schedule set at the time of protocol launch.

To calculate e the following logic can be used:

$$e = \left(\begin{array}{l} f : (a, b) \mapsto \left(\begin{array}{l} \text{let } x \text{ equal } \min \left\{ \lfloor \frac{d-l}{5} \rfloor - a + 1, 73 |b| \right\} \\ \sum_{i=1}^x \left(\begin{array}{l} \text{let } y \text{ equal } \left\lfloor t \frac{b \lfloor \frac{i}{73} \rfloor}{73} \right\rfloor \\ \begin{cases} y+1 & \text{if } i-1 < \left\lfloor t \sum b - \sum_{j=1}^{|b|} 73 \lfloor \frac{tb_j}{73} \rfloor \right\rfloor \\ y & \text{otherwise} \end{cases} \end{array} \right) \text{ if } x > 0 \\ 0 \text{ if } x \leq 0 \end{array} \right) \\ \text{let } z \text{ equal } \left(\begin{array}{l} \text{let } x \text{ equal } \min \left\{ \lfloor \frac{d-l-o}{365 \div 12} \rfloor + 1, q \right\} \\ \begin{cases} 0 & \text{if } x < 0 \\ \left\lfloor \frac{tp}{q} \right\rfloor & \text{if } x = 0 \text{ and } d-l \geq 0 \\ \left\lfloor \frac{xtp}{q} \right\rfloor & \text{otherwise} \end{cases} \end{array} \right) \\ \sum_{i=1}^{|a|} f(a_i, b_i) + z + \begin{cases} c & \text{if } d \geq l \\ 0 & \text{if } d < l \end{cases} \end{array} \right)$$

Where:

- a is a set of delays for token distribution schedules (set at protocol launch)
- b is a set of vesting distribution schedules (set at protocol launch)
- c is the amount of INDY unlocked upon Indigo mainnet launch (set at protocol launch)
- d is the date of the proposal's conclusion
- l is the date of the first epoch after the launch of Indigo mainnet (set at protocol launch)
- o is the offset for the start of Indigo's team distribution (set at protocol launch)
- p is the percentage of INDY total supply allocated to the Indigo team (set at protocol launch)
- q is the total number of months the Indigo team distribution lasts for (set at protocol launch)
- t is the total supply of INDY (set at protocol launch)

Vesting schedules defined by b are represented as a set of sets containing the percentage of token supply to be distributed per year, with each value in the subset representing an individual year. For example, consider the following set:

$$b = \{\{0.01, 0.02, 0.03\}, \{0.05, 0.1\}\}$$

This defines two vesting schedules (two being the size of the set b). The first vesting schedule in b , referenced as b_1 , describes a three-year vesting schedule (three being the size of the subset b_1), with the first year distributing 1% (0.01 being 1%) of total token supply, the second 2%, and the third year 3%, for a total of 6% (0.06 being the sum of all values in the subset b_1) of tokens distributed over the three years.

Knowing e , a proposal's approval status can be calculated using the formula:

$$q = \left\lfloor \frac{v_y}{\sqrt{e}} - \frac{v_n}{\sqrt{v_y + v_n}} \right\rfloor$$

Where:

- q is the vote threshold
- e is the amount of INDY in circulation at time of the proposal's conclusion
- v_y is the number of *yes* votes
- v_n is the number of *no* votes.

If q is larger than 0, the proposal is passed. If q is equal to or less than 0, the proposal is failed.

2.10.7 Governance Sharding

Upon creation of a proposal, multiple voting UTXOs can be created to maintain records of votes. Each voting UTXO represents a shard. The total number of shards that can be created is defined by the *Total Shards* protocol parameter.

After creating a proposal, the proposal's creator can create shards, up to the number of Total Shards, by depositing ADA and submitting transactions. If, after the proposal creation time plus the time defined by the *Proposing Period* protocol parameter, there are fewer shards created than Total Shards, then the proposal is considered expired.

The amount of ADA required to deposit to create an individual shard is x , as calculated and described in the [Minimum ADA to Create UTXO section](#). The proposal creator is required to deposit x ADA to create an individual shard. To prevent a proposal from expiring before all votes can be submitted, the proposal creator must deposit ADA totaling x multiplied by Total Shards. The deposited ADA is later returnable upon following correct voting procedures, as described in the [Governance Proposal Process](#) section.

To vote, an INDY staker selects a shard to track their allocation. Each shard records the total number of *yes* and *no* votes from users who voted using that shard. A shard can only record a vote from one user at a time. If a shard is in use by another user, then the user must select an alternative shard to use. If all shards are in use, then the user must wait until a shard becomes available.

At the end of the Voting Period, the shards can be closed. Upon closing, all votes from each shard can be tallied, and the final vote counts can be used to calculate whether the proposal has passed.

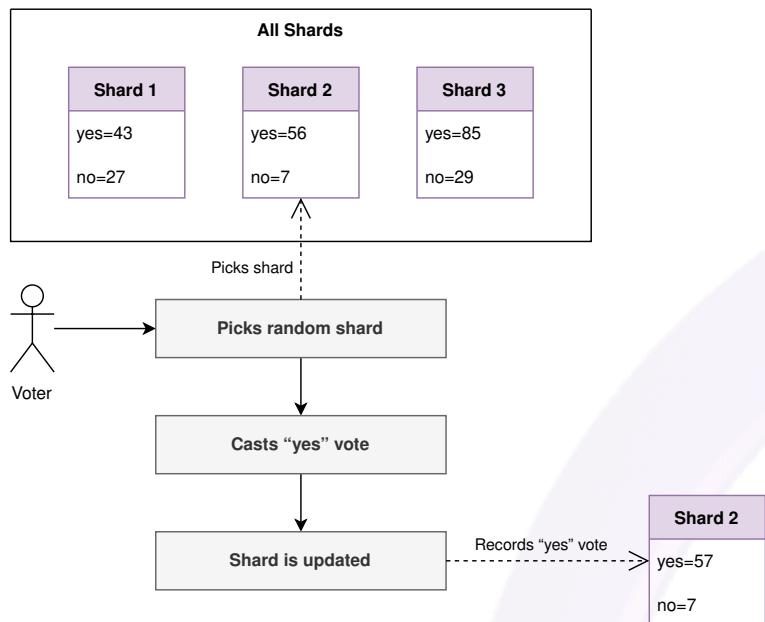

Figure 12: A voter selecting and casting their vote using a shard

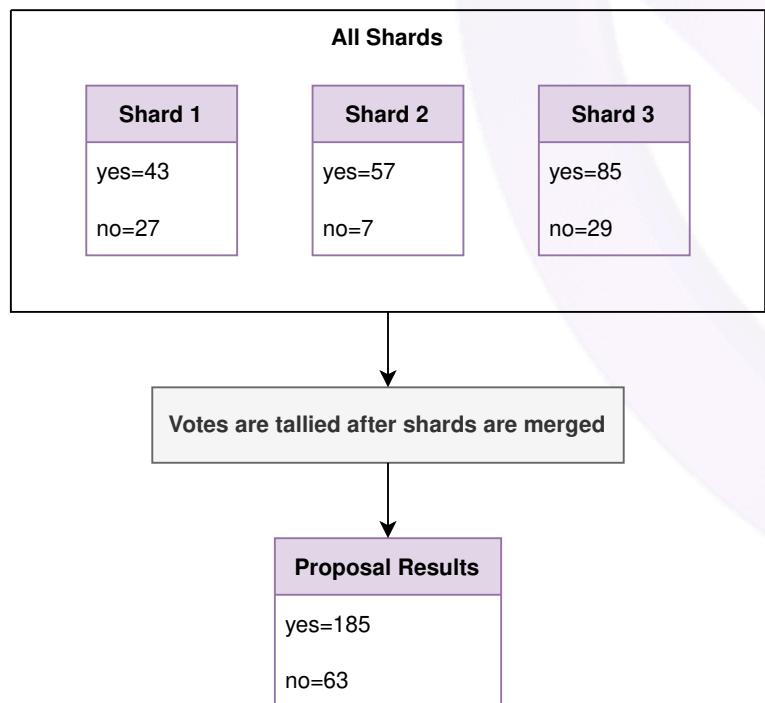

Figure 13: Shards being merged to tally votes after a Voting Period has ended

2.10.8 Governance Proposal Types

Users can submit the following type of proposals:

- **Whitelist an iAsset** – Propose that a new iAsset type be supported by the protocol. Attributes such as the MCR and Oracle price feed must be provided.
- **Update an iAsset** – Propose that an existing iAsset's MCR and/or Oracle price feed be updated. Nullifying an iAsset's Oracle price feed causes that iAsset to be no longer mintable; therefore, it is delisted from the protocol.
- **Text** – Propose that the Indigo DAO should adopt a proposal described textually. This formally records the DAO's intent on the blockchain but is not executed computationally, i.e., the proposal's executable message is non-actionable. A hash is stored on-chain, with the hash able to represent a Content Identifier (CID)¹² that references data on an external storage network.
- **Upgrade Protocol** – Propose that the protocol should be upgraded to a new version.
- **Update Protocol Parameters** – Propose that parameters describing protocol behavior be updated. Updateable parameters are shown in the [Protocol Parameters](#) table.

2.10.9 Protocol Parameters

Protocol parameters are updateable via proposals and define some behaviors of the protocol. They exist as a map of values inside a UTXO. Users and protocol functions can reference the values of the latest defined protocol parameters to utilize within transactions.

Table 6: Parameters that are updateable via an Update Protocol Parameters Governance Proposal

Parameter Name	Description
Effective Delay	The number of seconds after a passed proposal closes before it becomes eligible for execution.
Expiration Period	The maximum number of seconds allowed after a passed proposal closes for it to be executed. If the proposal isn't executed in time, then the proposal is considered expired.
Proposal Deposit	The amount of INDY that is required to be deposited to create a proposal. If a proposal passes, the INDY deposit is returnable to the owner. If a proposal fails, the INDY deposit is non-returnable, and instead is only transferable to the DAO Treasury .
Proposing Period	The maximum number of seconds allowed after a proposal is created for its shards to be created. If shards are not created by this time then the proposal fails and the creator loses their deposit.
Protocol Fee Percentage	The percentage of ADA to take as a protocol fee when withdrawing collateral from CDPs or redeeming SPL rewards.
Total Shards	The total number of Governance Shards to utilize during Voting Periods of proposals.
Voting Period	The number of seconds a proposal remains open for voting after being created.

2.10.10 Governance Proposal Process

Any user can create a proposal by depositing a fixed amount of INDY into the protocol. The amount of INDY required is determined by the value of the *INDY Deposit* protocol parameter.

Once submitted, the proposal becomes eligible for the proposal creator to create shards. After one or more shards are created for a proposal, it can be voted on by INDY stakers until that proposal's Voting Period has concluded.

¹²A CID is a self-describing [content-addressed identifier](#) containing 32 characters. A CID can be used to [lookup data](#) stored on decentralized networks such as [Filecoin](#).

Proposals are recorded on-chain with an executable message encoding the specific effects of each one. Upon execution, the proposal will be processed with the full privileges of the governance contracts.

The following steps outline the proposal lifecycle:

1. A user creates a new proposal by depositing an amount of INDY that equals the Proposal Deposit.
2. The proposal creator creates one or more shards, up to a maximum of Total Shards, by depositing ADA. All shards must be created before the Proposing Period ends for the proposal to pass.
3. The proposal enters the voting phase, where INDY stakers can vote (*yes/no*) using their staked INDY positions. INDY of the INDY stakers who vote remains locked until the *Voting Period* ends.
4. The Voting Period ends after more time has passed than the proposal's creation time, plus time defined by the Voting Period protocol parameter.
5. After the Voting Period has ended, the proposal can be closed by its creator.
6. If the proposal passes, its executable contents can be executed by users after a delay defined by the *Effective Delay* protocol parameter. The proposal must be executed prior to the time described by the *Expiration Period* protocol parameter; otherwise, the proposal will be considered expired and no longer executable.

Several actions can be taken against a proposal by users:

- **Create** – Creates a proposal conforming to one of the allowed [Governance Proposal Types](#).
- **Create Shard** – The owner of the proposal is expected to – and can – create one or more shards, up to a maximum of *Total Shards*. For a proposal to be eligible to pass, the number of shards created must equal Total Shards. A shard is created by depositing ADA alongside a request to create one. Shards can only be created from the creation of the proposal up until the *Proposing Period* ends. Creating shards after the Proposing Period will cause the transaction to fail.
- **Merge Shards** – Users can merge two or more shards created after the proposal's Voting Period ends and before the proposal is closed. Upon merging, the owner is eligible to receive back the ADA that was deposited to create each merged shard after the proposal is closed.
- **Close** – The owner of the proposal can close the proposal after its Voting Period ends if the number of shards created is equal to Total Shards, and after all shards have been merged. If the number of shards created is less than Total Shards, then the proposal cannot be closed until after the proposal expires. After the owner closes their proposal, they receive back any ADA that was deposited to create each shard. If a proposal expires before the owner closes the proposal, then any user can close the proposal.
- **Execute** – If a proposal is closed and has passed, any user can execute it. Upon execution, the protocol runs the executable message embedded within the proposal to apply changes to the protocol.

A proposal has the following states:

- **Created** – After a proposal is created it is available for the owner to create shards.
- **Open** – When a proposal has one or more shards available then it becomes available for INDY holders to vote on. If a proposal has at least one shard but less than *Total Shards*, the proposal is *Open*.
- **Active** – When a proposal has shards that equal *Total Shards*, all shards were created before the Proposing Period, and time has not exceeded its *Voting Period*, then the proposal is *Active*.
- **Ended** – When a proposal has exceeded its *Voting Period*, then the proposal is *Ended*.
- **Merged** – When all the proposal's shards have been merged, then the proposal is *Merged*.
- **Closed** – When a proposal is *Ended*, and after a user has made a submission for the proposal to close, then the proposal is *Closed*.
- **Passed** – When a proposal is *Closed* and the number of *yes* votes exceeds the quorum threshold, then the proposal is *Passed*.
- **Failed** – When a proposal is *Closed* and the number of *yes* votes does not exceed the quorum threshold, then the proposal is *Failed*.

- **Expired** – When a proposal has exceeded its *Execution Period* without being executed, if the created shards are fewer than Total Shards after the Voting Period, or if shards have been created after the Proposing Period, then the proposal is *Expired*.
- **Executed** – When a proposal is *Passed* and not *Expired*, then any user can execute the proposal. The proposal then becomes *Executed*.

2.10.11 Indigo DAO Treasury

The Indigo DAO owns and controls a DAO Treasury (the “Treasury”). Upon minting of INDY, a portion of INDY (the amount is defined at protocol launch) is sent to the Treasury. The INDY in the Treasury is intended to be used for future versions of the protocol and controlled by the [governance process](#).

To permanently identify the Indigo DAO on the Cardano blockchain, a NFT is minted as the official Indigo DAO identity token (“identity token”) and held in the Treasury. The identity token is transferred to wherever the latest version of the Treasury lives. The protocol transfers the identity token and INDY in the Treasury upon future protocol upgrades.

2.10.12 Protocol Upgrade

Indigo is designed to be continually and incrementally upgraded. Instead of releasing distinct protocols that users may interact with individually, the Indigo Protocol exists as a singular protocol whose underlying validators may periodically be updated. From a user’s perspective, the interaction is seamless, since they will only interact with one protocol, regardless of the version of Indigo Protocol that is live on the Cardano blockchain.

A single protocol has been launched, and new features will be added to Indigo via approval from Members. Protocol upgrades are driven by the [governance process](#). To suggest new features, a Text proposal and development request must first be approved and authorized by the DAO. A development firm such as Indigo Laboratories will then begin work on building software to implement the new features.

When software is ready for deployment, a request to upgrade is submitted to Indigo. Members can inspect the new code requested to be deployed and either approve or reject the proposal. Upon approval, the developing entity of the software can deploy the code to Cardano, and Indigo will be automatically upgraded to a new version. However, the code must match the code approved by Members, otherwise Indigo will not recognize the new features as authentic, and no upgrade will take place.

After deployment and approval, individual user positions can be migrated from the old version to the new one. Some features may not be available until the user has migrated their positions. For example, if a user owns a CDP, they will be unable to add collateral to their CDP until they migrate their CDP to the new version of Indigo. To migrate a CDP, a user will have to pay a small transaction fee in the form of ADA and submit the migration request via the Indigo Web App. If a user chooses not to migrate a CDP, they will not be able to deposit more collateral or mint more iAsset; their CDP may become at risk of liquidation. Another user may opt to migrate a CDP subject to liquidation to perform the liquidation and confiscate the underlying collateral, with the original CDP owner losing their collateral.

2.11 Protocol Profit Sharing

As users create and close CDPs, and as CDPs are liquidated, a fee is collected. Members are rewarded by receiving a share of the collected fees. The fee is set to 2% and modifiable by vote of Members.

When a fee is collected, it is sent to the Collector smart contract. The Collector’s purpose is to collect protocol fees and distribute them to INDY stakers. Users who stake their INDY are eligible to a share of all collected protocol fees, proportional to their share of total INDY staked.

The Collector maintains a collection of UTXOs that can be used to store ADA. When a protocol fee is collected, such as during withdrawal of a liquidation reward, the user selects a UTXO from the Collector to send the fee to. The amount of ADA required to deposit to create a Collector UTXO is x , as calculated and described in the [Minimum ADA to Create UTXO section](#). A Collector UTXO can be created by any user who deposits x ADA. Once deposited, a new UTXO is added to the Collector and the ADA cannot be withdrawn.

Users can request to gather fees from Collector UTXOs and collectively send them to the Staking Manager who is responsible for allowing INDY stakers to withdraw their share of owed fees, and will only accept deposits of fees if there are one or more INDY stakers. If no INDY is staked, then user requests to transfer fees from the Collector to the Staking Manager will fail.

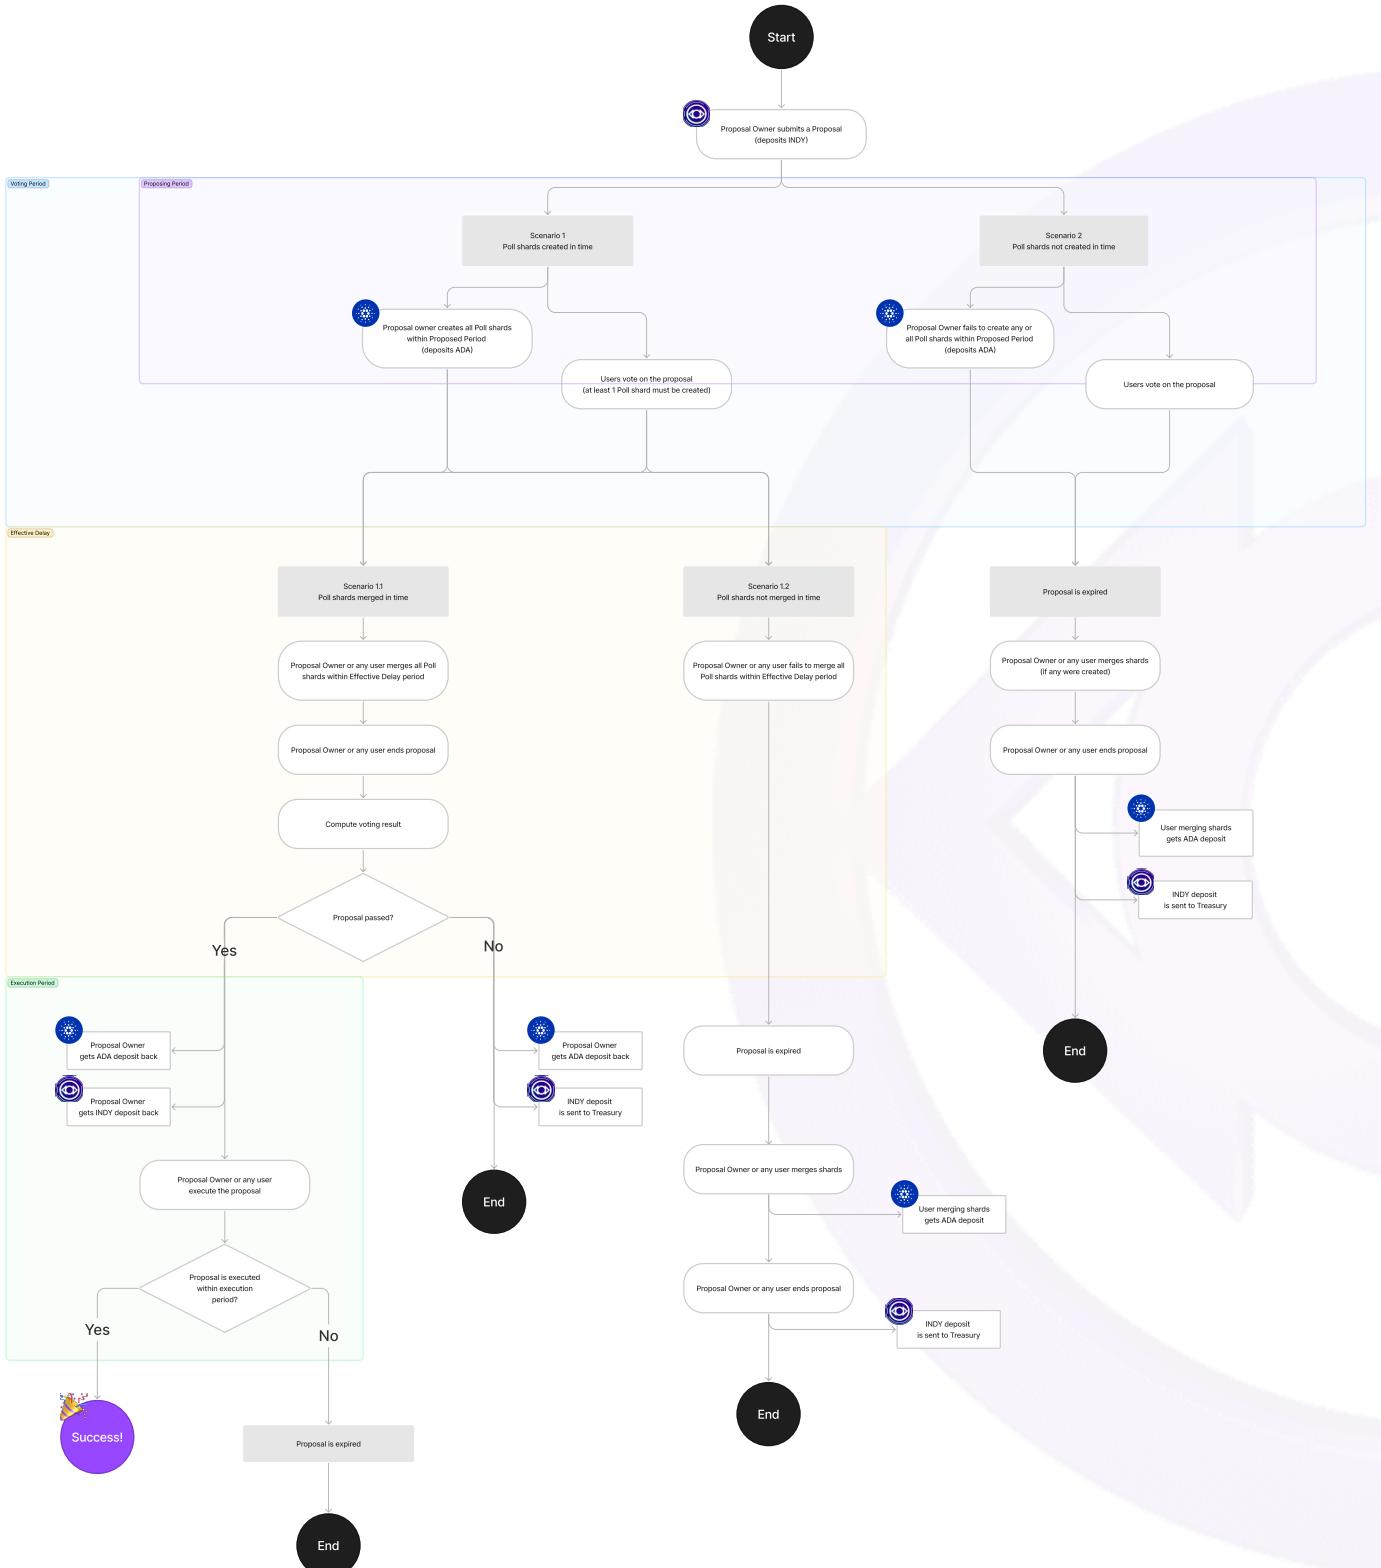

Figure 14: Illustration of the proposal lifecycle

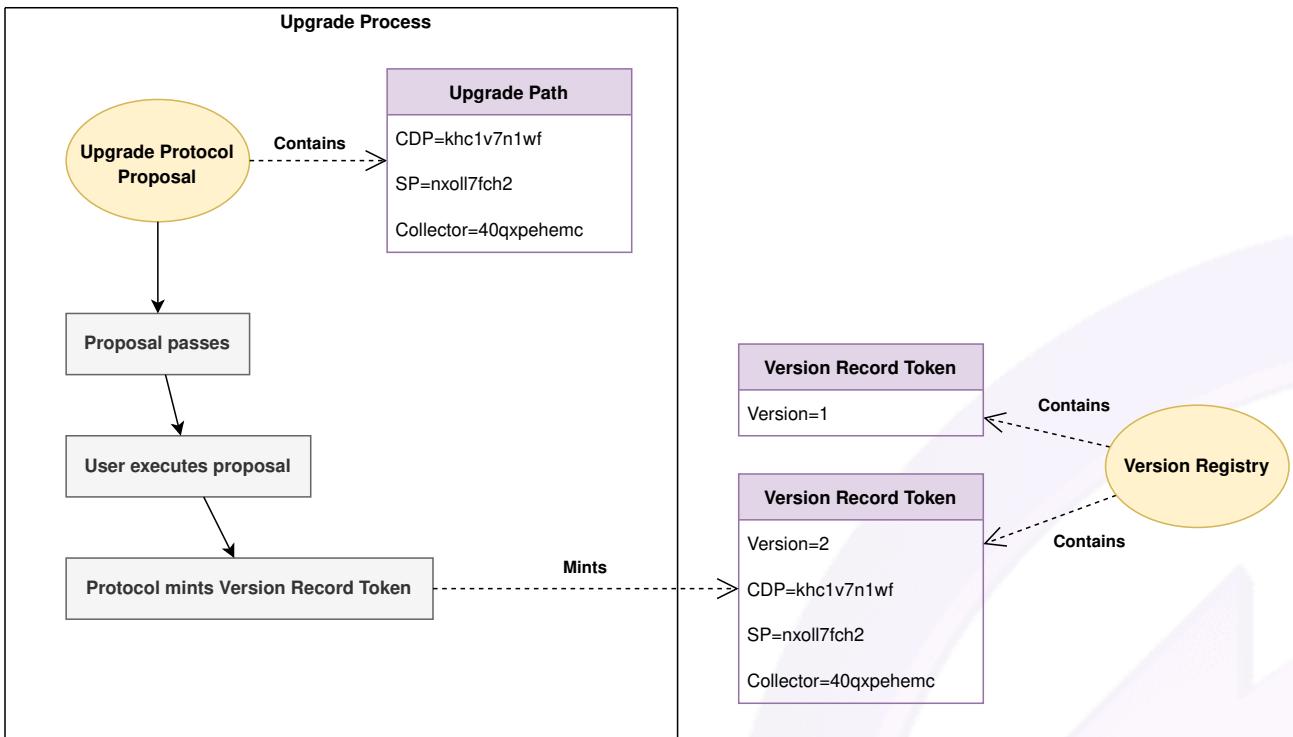

Figure 15: Illustration of an Upgrade Protocol proposal upgrading the CDP, SP, and Collector contracts

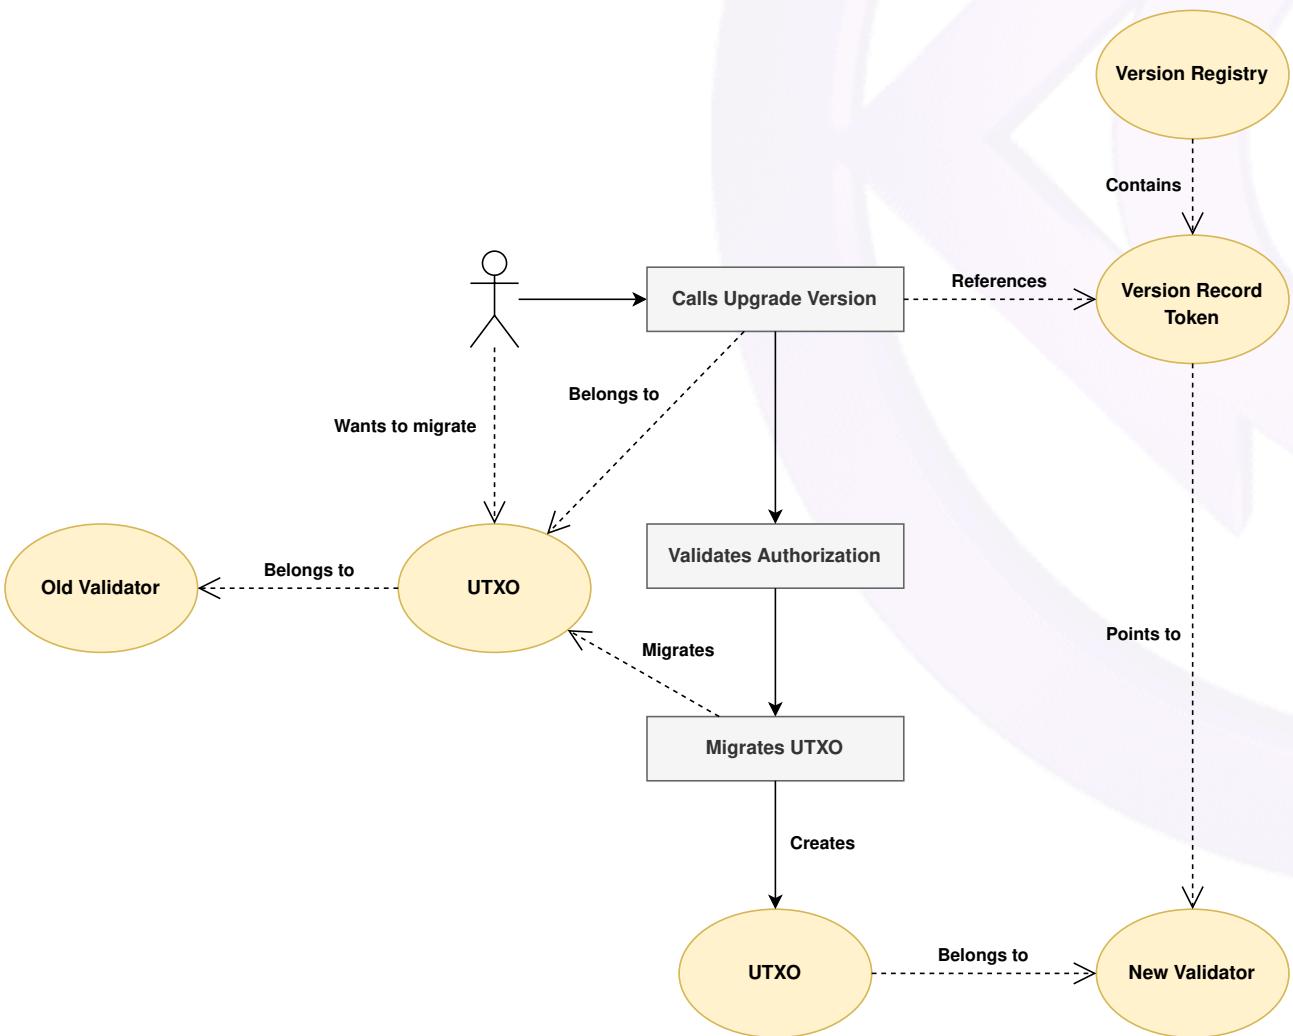

Figure 16: Illustration of a UTXO migrating from an old validator to a new validator

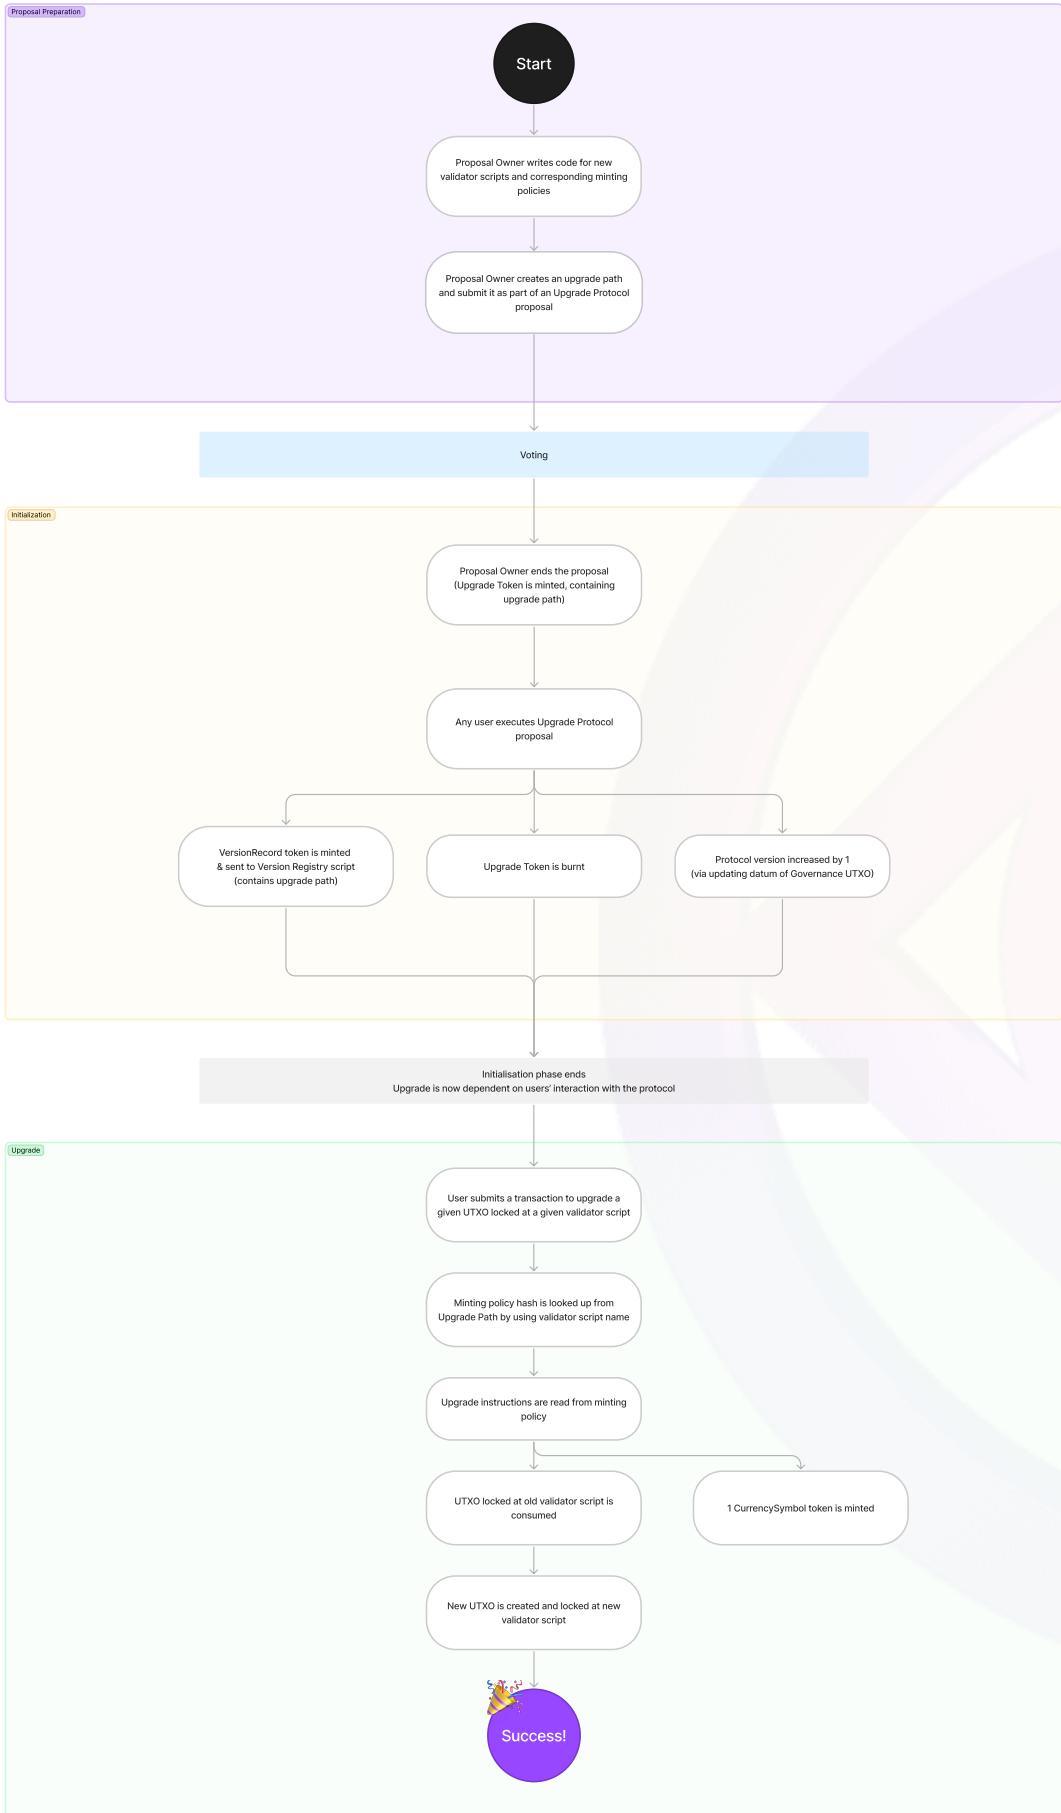

Figure 17: The process to upgrade the protocol

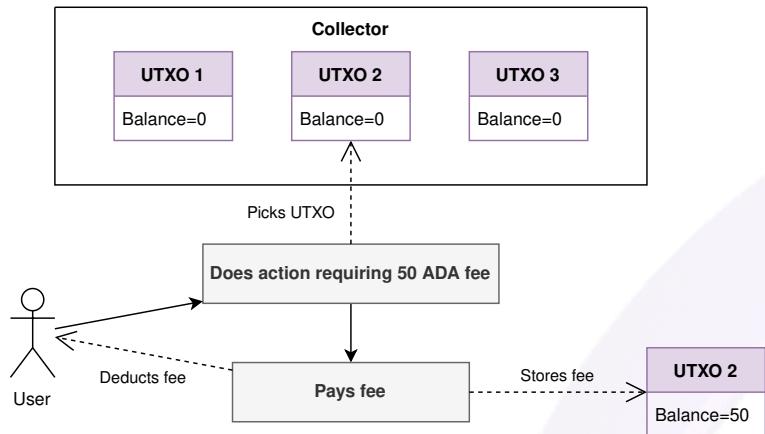

Figure 18: A user paying a fee to the Collector

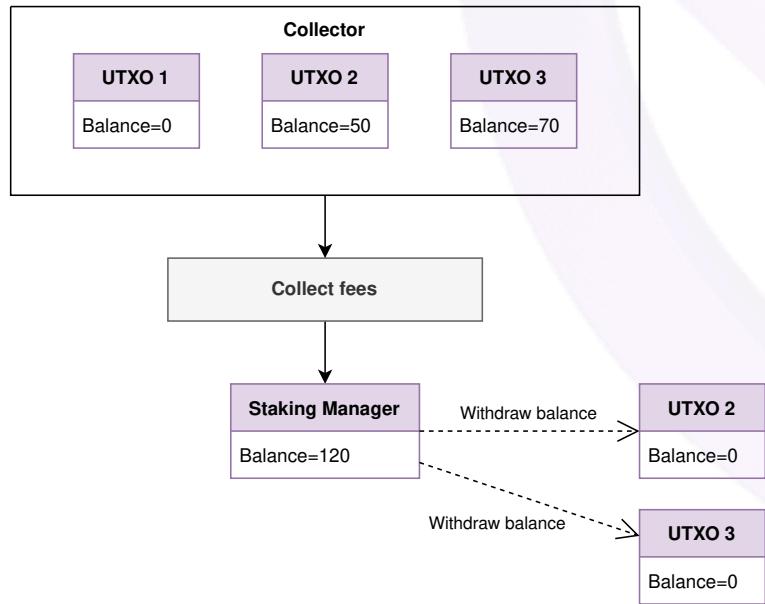

Figure 19: Transferring collected fees to the Staking Manager

The Staking Manager keeps track of the number of INDY that are staked as well as a snapshot value. The snapshot value is a running total (with a precision of six decimals) of reward deposits updated each time ADA is transferred from the Collector to the Staking Manager, and can be calculated using:

$$a = b + \frac{c}{d}$$

Where:

- a is the new snapshot value to be stored by the Staking Manager, truncated to six decimals
- b is the current snapshot value stored by the Staking Manager
- c is the amount of ADA deposited into the Staking Manager from the Collector
- d is the total amount of INDY staked in the Staking Manager

The snapshot value is initially set to zero. When a user stakes INDY, the current snapshot value is stored in the INDY staker's position, and the total amount of INDY staked is updated in the Staking Manager. When an INDY staker updates or closes their position, all rewards are withdrawn. INDY staker rewards can be calculated using:

$$a = d(b - c)$$

Where:

- a is the amount of ADA reward the user is owed
- b is the current snapshot value stored by the Staking Manager
- c is the snapshot value when the user staked their INDY
- d is the amount of INDY the user has staked

3 Smart Contract Design

In Cardano's eUTXO model¹³, each transaction has inputs and outputs. An input is a UTXO that is an output of another transaction. Users interact with the protocol by performing actions and submitting transactions containing those actions to Protocol Endpoints. Submitted transactions are validated by the protocol's smart contracts (also known as validators). If a transaction is successfully validated (i.e., permitted), then an action is put into effect by the transaction's execution.

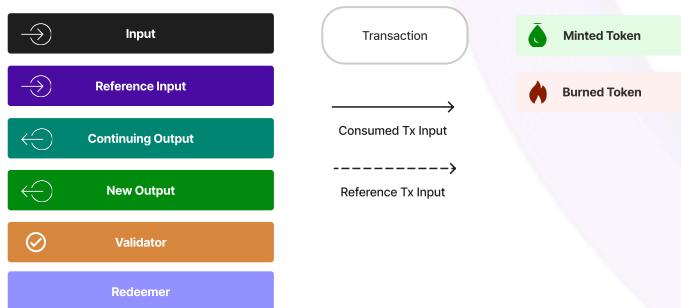

Figure 20: Legend for Protocol Endpoint transaction examples

Protocol Endpoints allow users to interact with the protocol by performing a specific action such as [opening a CDP](#), [submitting a proposal](#), [depositing iAssets in a SP](#), etc. A Protocol Endpoint can take input in the form of UTXOs. Input is provided either by consuming or referencing. To consume a UTXO is to spend the UTXO in whole within the transaction. By consuming the UTXO it allows change to the state of that UTXO, such as updating the balance. To reference a UTXO is to read the UTXO without change. Only one user can consume a single UTXO at a time, whereas many users can simultaneously reference UTXOs.

Protocol Endpoints may perform actions in the form of minting or burning. Minting a token creates a new token and allows it to be used as input. Upon minting, the token may be stored in a UTXO containing datum

¹³Cardano utilizes the eUTXO model to perform arbitrary logic permitted by smart contracts.

that can be read for additional information. Burning a token destroys an existing token, making it no longer usable as input.

Outputs are UTXOs that are created as an effect of a transaction. For example, a Protocol Endpoint may create an output to represent a user position or a pool of tokens. After an output is created it can be used as an input.

Following are details for each Indigo smart contract, their tokens issued, parameter inputs, and outputs.

For the described smart contract parameters, token types are in the form of *Value.AssetClass*¹⁴. The smart contracts look for the UTXO with the token type and may read the datum of that UTXO for additional information.

3.1 CDP

The CDP contracts are used to store the collateral used to mint iAssets. There are two contracts for managing CDPs: CDPCreator and CDP. The CDPCreator validates the creation of a user's CDP UTXO. The CDP contract is used to manage a user's individual position by validating actions such as storing collateral, minting iAssets, and performing SPL.

Table 7: CDP native tokens

Name	Description	Minting Policy
CDPCreatorNFT	Identifies the authentic CDPCreator output Validators ensure that this NFT always stays at the CDPCreator output	The protocol mints more than 1 token at initialization
CDPToken	Identifies an authentic CDP output	The transaction must spend CDPCreatorNFT or consume a CDPToken
iAssetToken	Identifies an authentic iAsset output, where datum is stored defining iAsset information including the OracleAssetNFT used to reference the latest price Validators ensure that this token always stays at an iAsset output	The transaction must consume GovNFT
iAssets (iBTC, iETH, etc.)	Synthetic version of BTC, ETH, etc.	The transaction must consume a CDPToken

Table 8: CDP token inputs

Type	Description	Datum
OracleAssetNFT	The NFT managed by an Oracle provider that's used to record price information for an iAsset	<i>odPrice</i> : The price with six decimals of precision <i>odExpiration</i> : The timestamp in which the oracle price expires

3.1.1 CDPCreator Parameters

- **cdpCreatorNFT** :: CDPCreatorNFT. NFT for identifying authentic CDPCreator output.
- **cdpAssetCs** :: CurrencySymbol. Currency symbol for the minting policy of iAssets.
- **cdpAuthTk** :: CDPToken. Token for identifying authentic CDP output.
- **iAssetAuthTk** :: iAssetToken. Token for identifying authentic iAsset output including datum with the iAsset name, MCR, and OracleAssetNFT reference to find the latest price for the asset.

¹⁴An asset class is identified by currency symbol and token name.

- `versionRecordToken` :: `VersionRecordToken`. Token for identifying the version record for a protocol upgrade.
- `cdpScriptHash` :: `ValidatorHash`. Hash of CDP script, used for verifying the output of a CDP.

3.1.2 CDP Parameters

- `cdpAuthToken` :: `CDPToken`. Token for identifying authentic CDP output.
- `cdpAssetSymbol` :: `CurrencySymbol`. Currency symbol for the minting policy of iAssets.
- `iAssetAuthToken` :: `iAssetToken`. Token for identifying authentic iAsset output.
- `stabilityPoolAuthToken` :: `StabilityPoolToken`. Token identifying authentic SP output.
- `versionRecordToken` :: `VersionRecordToken`. Token for identifying the version record for a protocol upgrade.
- `upgradeToken` :: `UpgradeToken`. Token for identifying proposal Upgrade tokens to update iAsset output.
- `collectorValHash` :: `ValidatorHash`. The validator hash for the Collector contract.
- `govNFT` :: `GovNFT`. NFT for identifying authentic governance parameters.
- `spValHash` :: `ValidatorHash`. The validator hash for the SP contract.

Table 9: CDP outputs

Type	Description	Datum	Values
<code>CDPCreator</code>	Many CDPCreator outputs exist for the protocol To create a CDP output, this output must be consumed		<code>CDPCreatorNFT</code> : 1
<code>CDP</code>	Each CDP output represents an individual position	<code>cdpOwner</code> : The public key hash that owns this CDP <code>cdpIAsset</code> : The type of iAsset associated with this CDP <code>cdpMintedAmount</code> : Amount of iAsset minted from this position	<code>CDPToken</code> : 1 <code>ADA</code> : collateral locked in this position
<code>iAsset</code>	Each iAsset output represents an iAsset	<code>iaName</code> : the name of iAsset <code>iaMinRatio</code> : The minimum collateral ratio of iAsset <code>iaPrice</code> : Either the final price for the delisted asset or the OracleAssetNFT used to reference the price feed	<code>iAssetToken</code> : 1

3.1.3 CDP Endpoints

CDP: Open Creates a CDP associated with an iAsset type

Type	Amount	Description
<code>Redeemer</code>	N.A.	CreateCDP, takes as parameters a public key hash corresponding to a user's wallet, amount of iAssets to mint, and ADA collateral to deposit
<code>Consume</code>	1	CDPCreator UTXO
<code>Consume</code>	1+	ADA to be used as collateral

Type	Amount	Description
Reference	1	iAsset UTXO that identifies the iAsset to mint
Reference	1	UTXO containing the OracleAssetNFT with a datum describing the iAsset price
Mint	∞	The minted iAsset tokens (dependent on the ADA deposited, iAsset MCR determined from the iAsset UTXO, and iAsset price)
Mint	1	CDPToken that identifies a user's position
Output	1	CDPCreator UTXO
Output	1	CDP UTXO that represents a user's CDP
Output	1	The UTXO sent to the user's wallet containing the minted iAsset

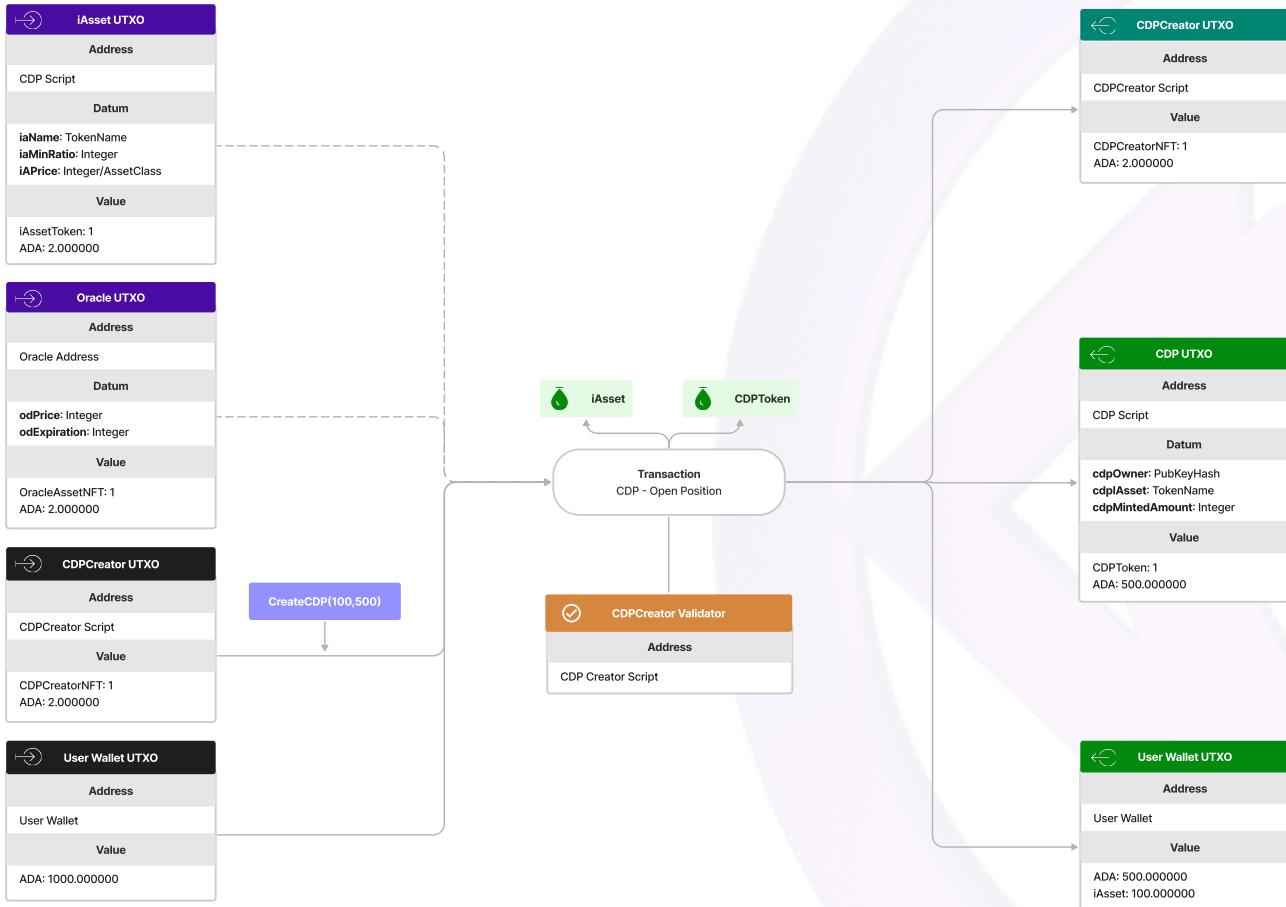

Figure 21: Example of creating a CDP with 500 ADA and minting 100 iAsset

CDP: Deposit Collateral Deposit ADA collateral into an existing CDP

Type	Amount	Description
Redeemer	N.A.	AdjustCDP
Consume	1	CDP UTXO that represents the user's current position
Consume	1+	UTXOs containing ADA from the user's wallet to be used as collateral
Reference	1	iAsset UTXO that serves to identify the iAsset that the CDP is for
Output	1	CDP UTXO that represents the user's adjusted CDP
Output	1	New UTXO to the user wallet returning change (if any)

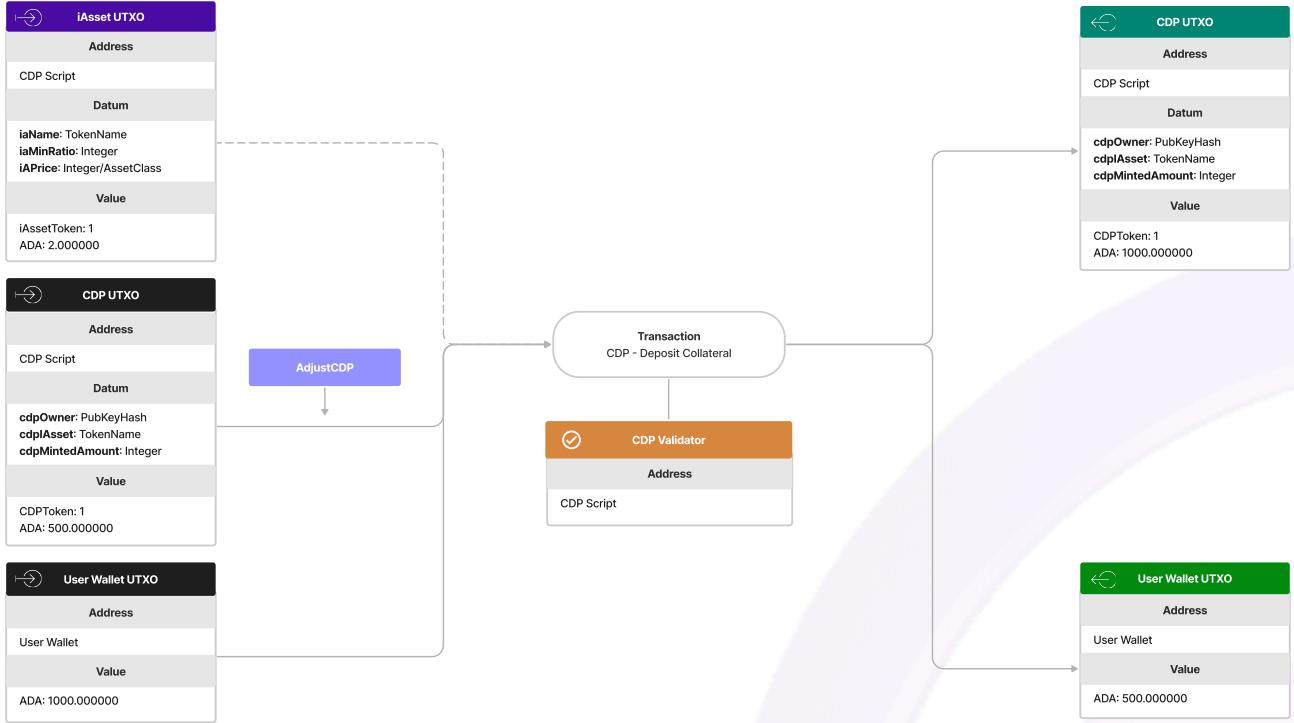

Figure 22: Example of depositing an additional 500 ADA into an existing CDP

CDP: Withdraw Collateral

Withdraw ADA collateral from an existing CDP

Type	Amount	Description
Redeemer	N.A.	AdjustCDP
Consume	1	CDP UTXO that represents the user's current position
Consume	1	Collector UTXO that may already contain fees previously collected
Reference	1	iAsset UTXO that serves to identify the iAsset should be minted
Reference	1	UTXO containing the OracleAssetNFT with a datum describing the iAsset price
Output	1	CDP UTXO that represents the user's adjusted position
Output	1	Collector UTXO that contains a portion of the withdrawn collateral (taken as a fee)
Output	1	A new UTXO to the user wallet containing the withdrawn collateral

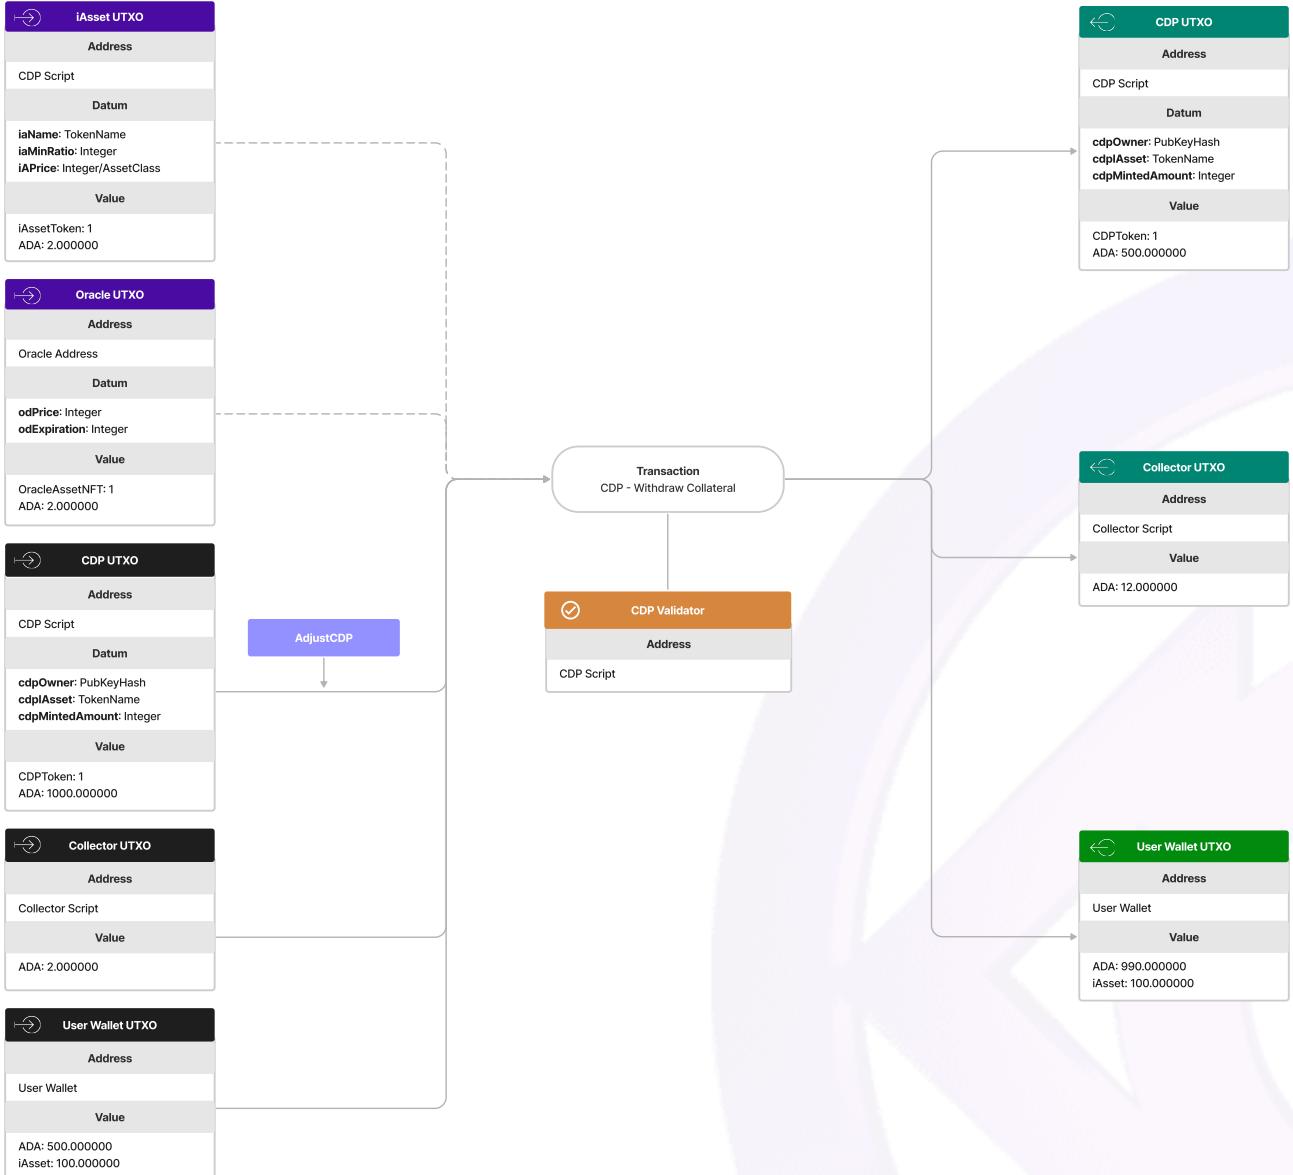

Figure 23: Example of withdrawing 500 ADA from a CDP and paying a 10 ADA fee

CDP: Close Closes an existing CDP

Type	Amount	Description
Redeemer	N.A.	CloseCDP
Redeemer	N.A.	Collect
Consume	1	CDP UTXO that represents the user's current position
Consume	1	Collector UTXO that may already contain fees previously collected
Consume	1+	UTXOs from the user's wallet containing iAsset tokens of the same type as the CDP
Reference	1	iAsset UTXO that serves to identify the iAsset the CDP is for
Reference	1	UTXO containing the OracleAssetNFT with a datum describing the iAsset price
Burn	∞	iAssets that were sent by the user
Burn	1	CDPToken
Output	1	Collector UTXO that contains a portion of the CDP collateral (taken as a fee)

Type	Amount	Description
Output	1	A new UTXO to the user wallet containing the total collateral (minus the fee)

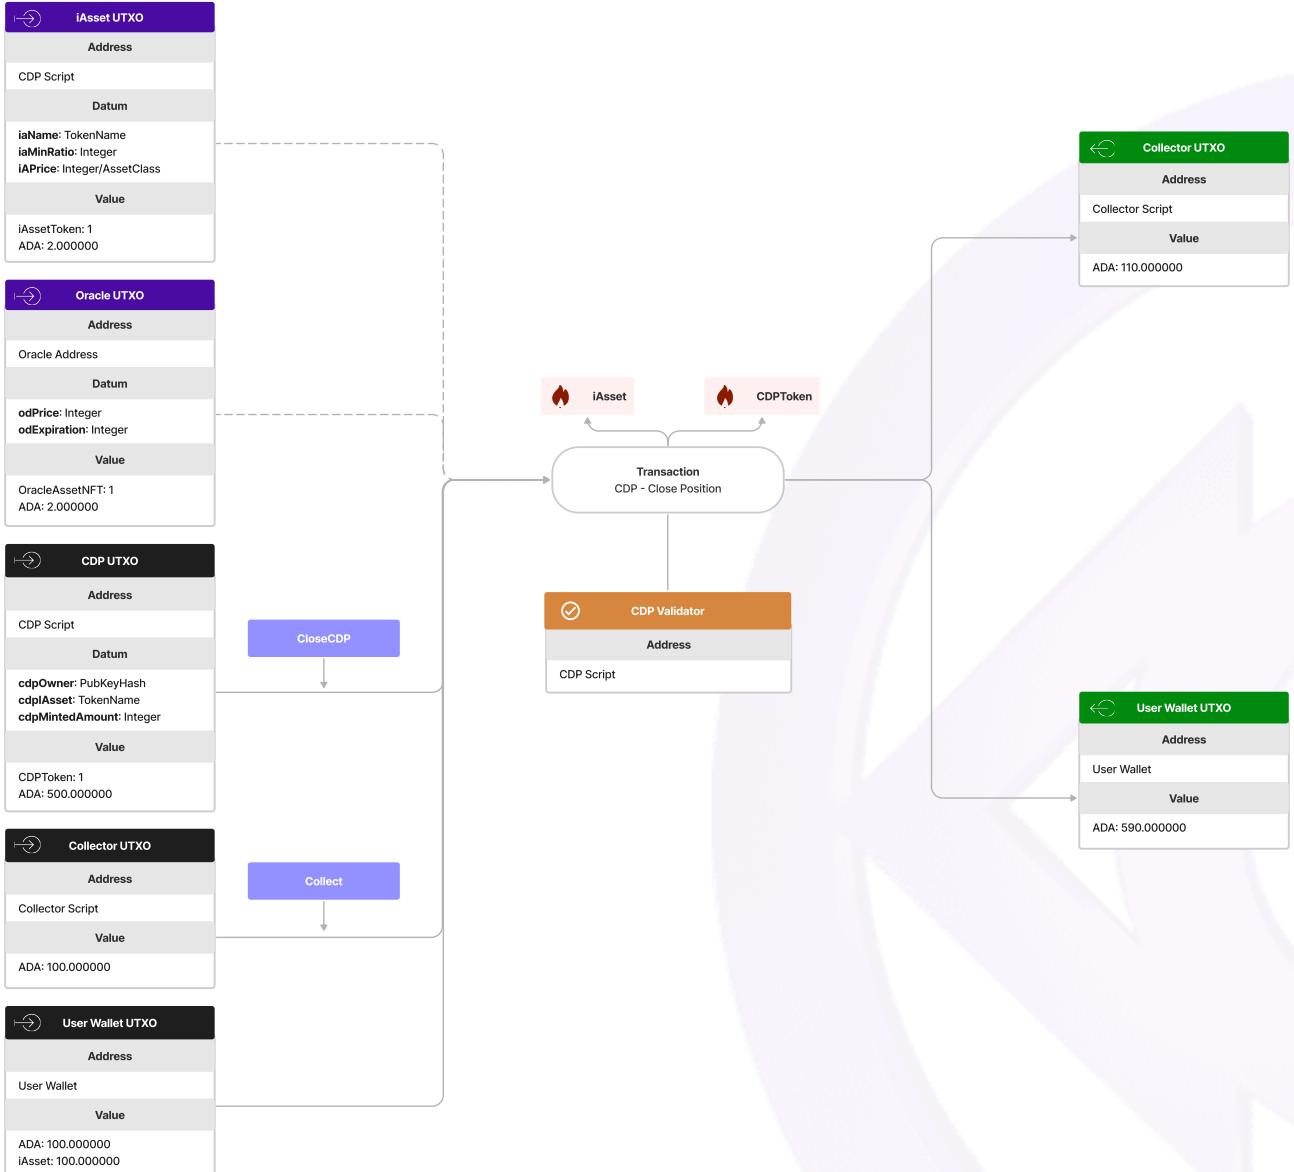

Figure 24: Example of closing a CDP and paying a 10 ADA fee

CDP: Mint iAsset Mints iAsset using an existing CDP

Type	Amount	Description
Redeemer	N.A.	AdjustCDP
Consume	1	CDP UTXO that represents the user's current position
Reference	1	iAsset UTXO that serves to identify the iAsset the CDP is for
Reference	1	UTXO containing the OracleAssetNFT with a datum describing the iAsset price
Mint	∞	iAsset tokens the user selected to mint
Output	1	CDP UTXO that represents the user's adjusted CDP
Output	1	A new UTXO to the user wallet containing the newly minted iAsset tokens

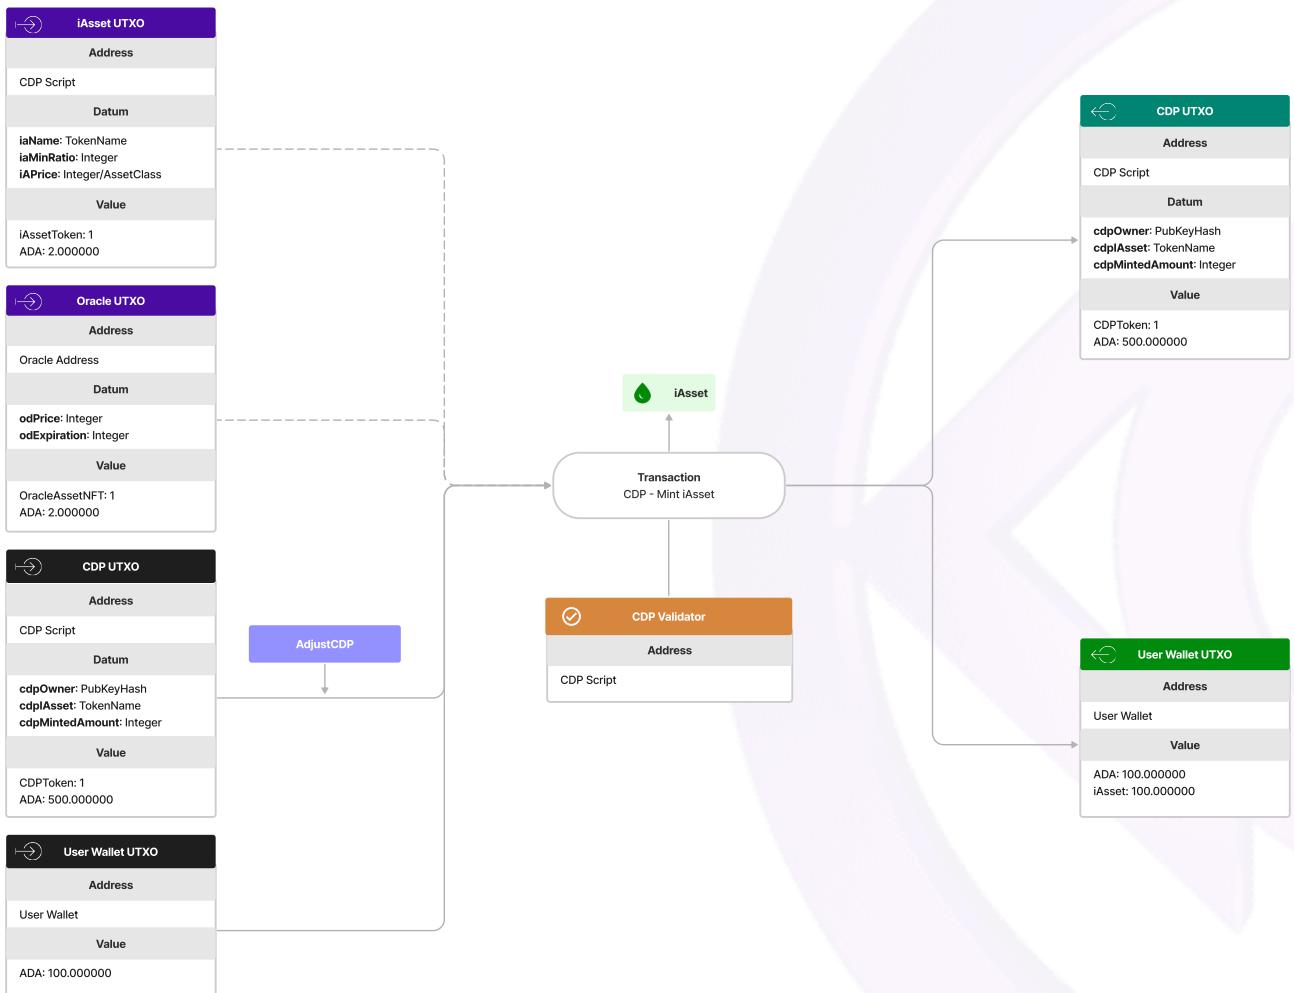

Figure 25: Example of using a CDP to mint 100 iAsset

CDP: Burn iAsset Burns iAsset using an existing CDP

Type	Amount	Description
Redeemer	N.A.	AdjustCDP
Consume	1	CDP UTXO that represents the user's current position
Consume	1+	UTXOs from the user's wallet containing the iAsset tokens to be burned
Reference	1	iAsset UTXO that serves to identify the iAsset that the CDP is for
Burn	∞	The iAsset tokens the user requested to burn
Output	1	CDP UTXO that represents the user's adjusted position
Output	1	New UTXO to the user wallet returning change (if any)

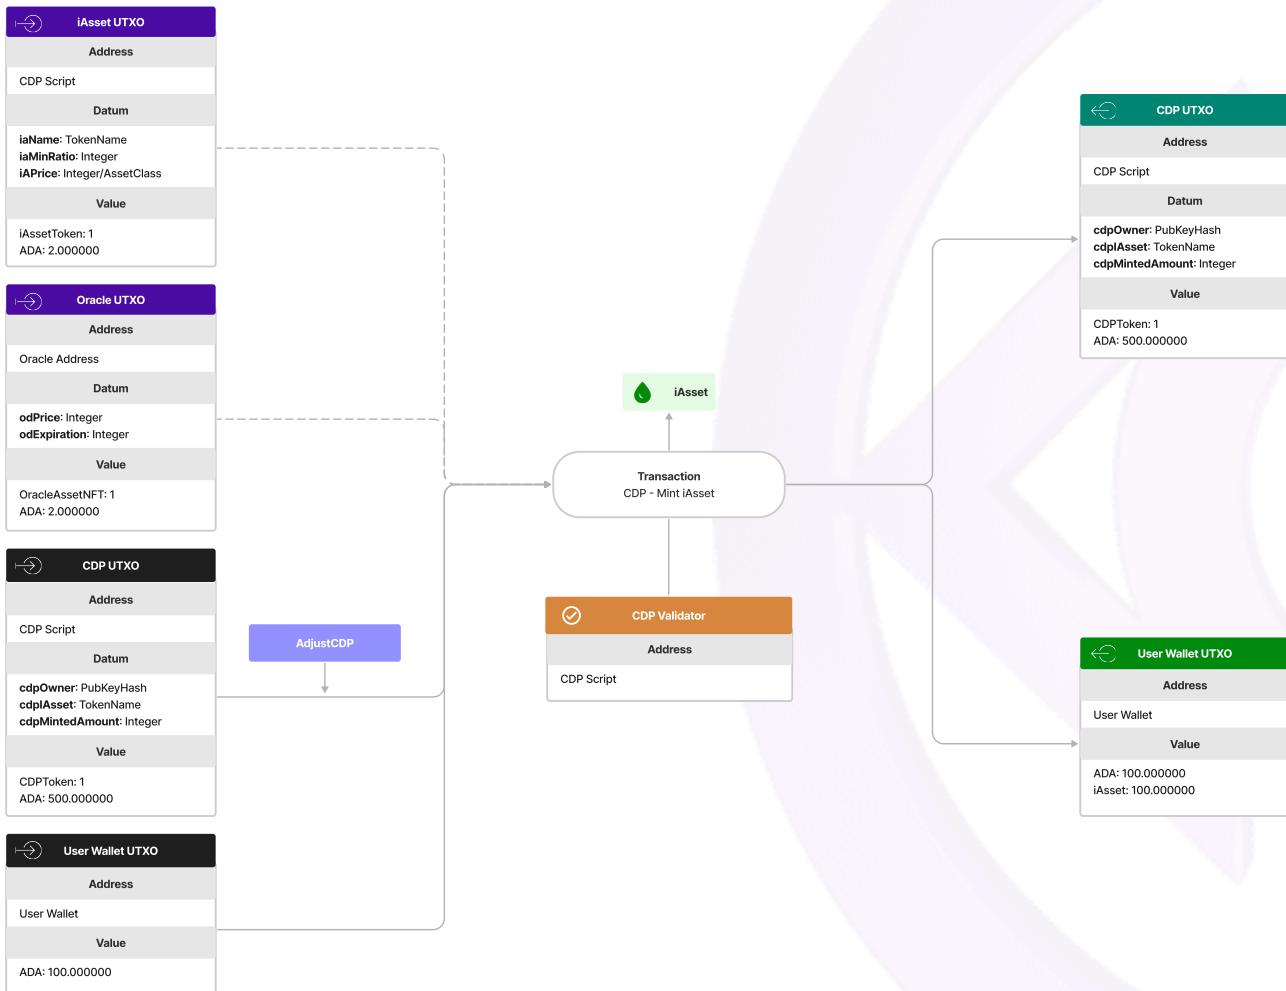

Figure 26: Example of using a CDP to burn 50 iAsset

CDP: Freeze Makes an existing CDP no longer interactable by its creator if it is insolvent

Type	Amount	Description
Redeemer	N.A.	FreezeCDP
Consume	1	CDP UTXO that represents the user's current position
Reference	1	iAsset UTXO that serves to identify the iAsset the CDP is for
Reference	1	UTXO containing the OracleAssetNFT with a datum describing the iAsset price

Type	Amount	Description
Output	1	CDP UTXO that represents the frozen CDP
Output	1	New UTXO to the user wallet returning change (if any)

CDP: Liquidate Withdraws ADA collateral from a CDP and transfers it to a SP if the CDP is frozen

Type	Amount	Description
Redeemer	N.A.	Liquidate
Redeemer	N.A.	LiquidateCDP
Consume	1	CDP UTXO that represents the frozen CDP to liquidate
Consume	1	SP UTXO that contains iAsset tokens to repay the debt
Burn	0/1	If all debt is repaid, then the CDPToken of the frozen CDP is burned
Output	1	SP UTXO that with the added collateral from the frozen CDP

CDP: Merge Closes one or more CDPs and transfers all CDP state into a single CDP

Type	Amount	Description
Redeemer	N.A.	NergeCDPs
Redeemer	N.A.	MergeAuxiliary, takes a CDP UTXO as a parameter which identifies the main UTXO to keep and have others UTXOs merged into
Consume	2+	CDP UTXOs of the frozen CDPs
Output	1	CDP UTXO representing all the frozen CDPs combined

3.2 Stability Pool

The SP contract is used as a pool of iAssets to be used for liquidation. It is important to understand how the Snapshot works to understand how the liquidations and account withdrawals work.

Table 19: Stability Pool native tokens

Name	Description	Minting Policy
StabilityPoolToken	Identify the authentic StabilityPool output	The transaction must spend GovNFT
AccountToken	Identify an authentic StabilityPoolAccount output	The transaction must spend StabilityPoolToken

3.2.1 Stability Pool Parameters

- `assetSymbol` :: `CurrencySymbol`. The minting policy for iAssets.
- `stabilityPoolToken` :: `StabilityPoolToken`. The token identifying an authentic SP output.
- `accountToken` :: `StabilityPoolToken`. The token identifying an authentic SP Account output.
- `cdpToken` :: `CDPToken`. Token for identifying authentic CDP output.
- `versionRecordToken` :: `VersionRecordToken`. Token for identifying the version record for a protocol upgrade.
- `collectorValHash` :: `ValidatorHash`. The validator hash for the collector contract.
- `govNFT` :: `GovNFT`. NFT for identifying authentic governance parameters

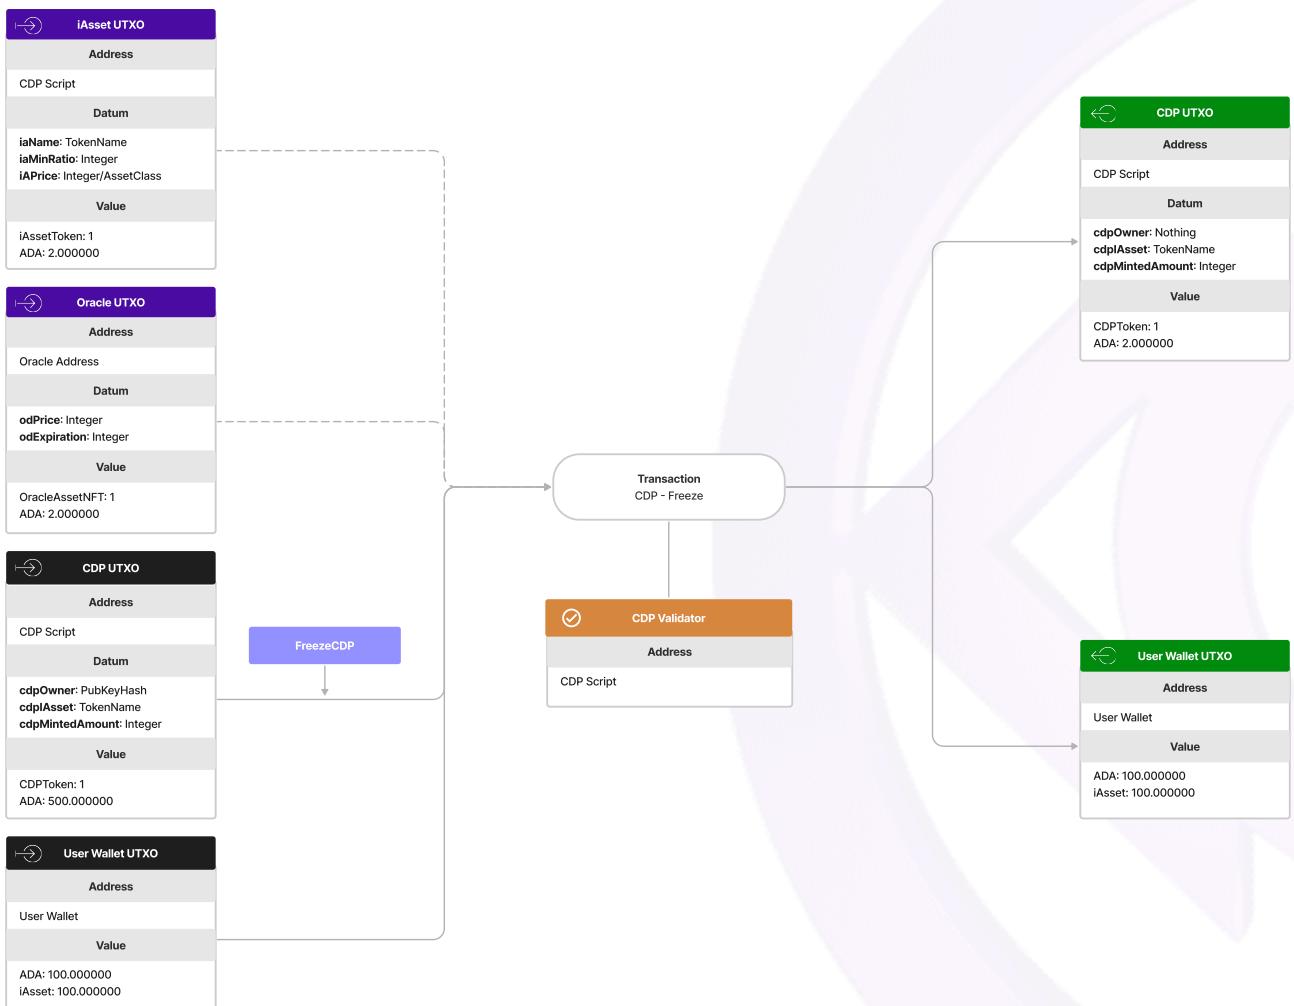

Figure 27: Example of freezing a CDP, thereby removing the creator as an owner

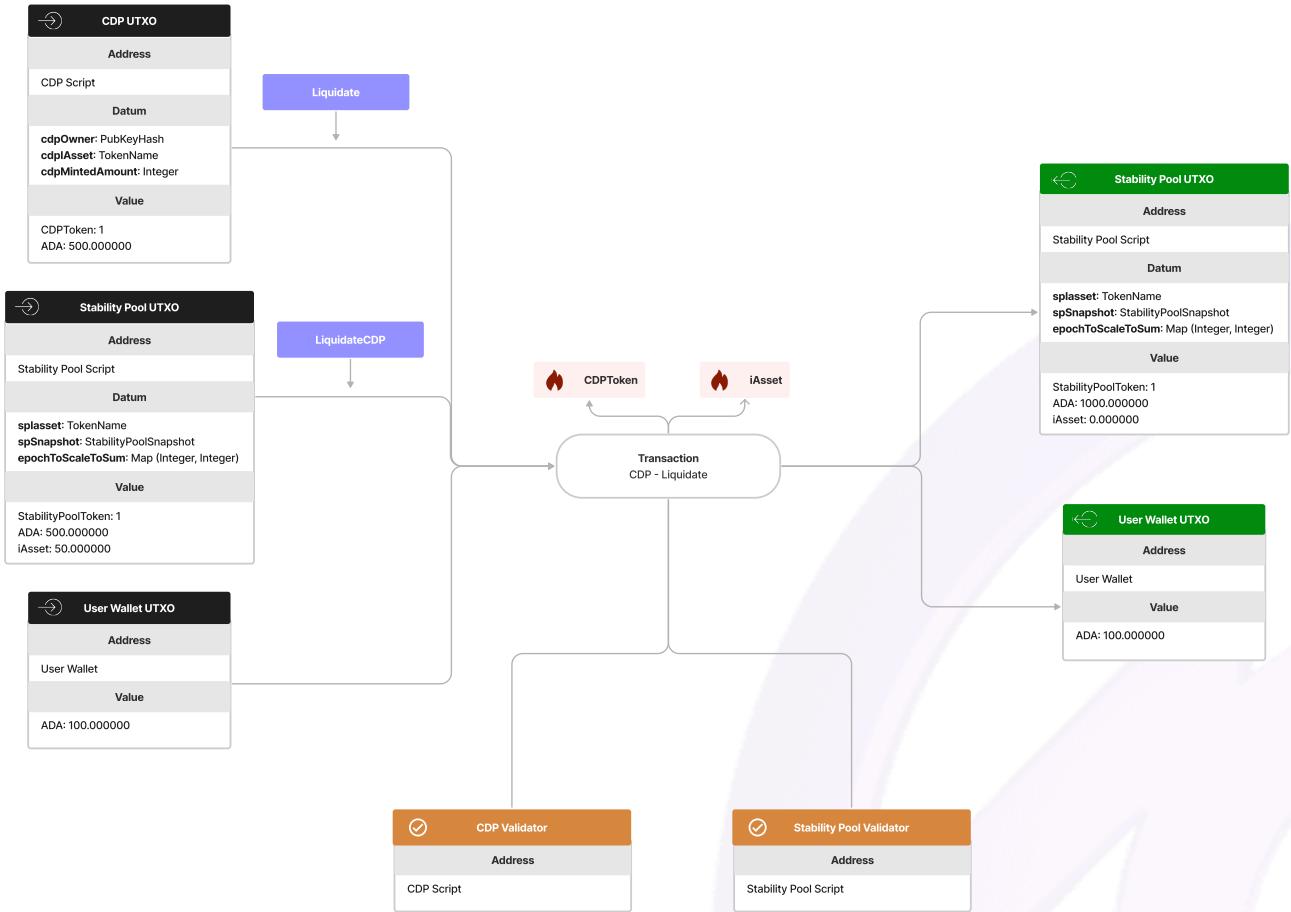

Figure 28: Example of a CDP with a debt of 50 iAsset and collateral of 500 ADA being liquidated, with the collateral being transferred to the Stability Pool, and the iAsset from the Stability Pool being burned

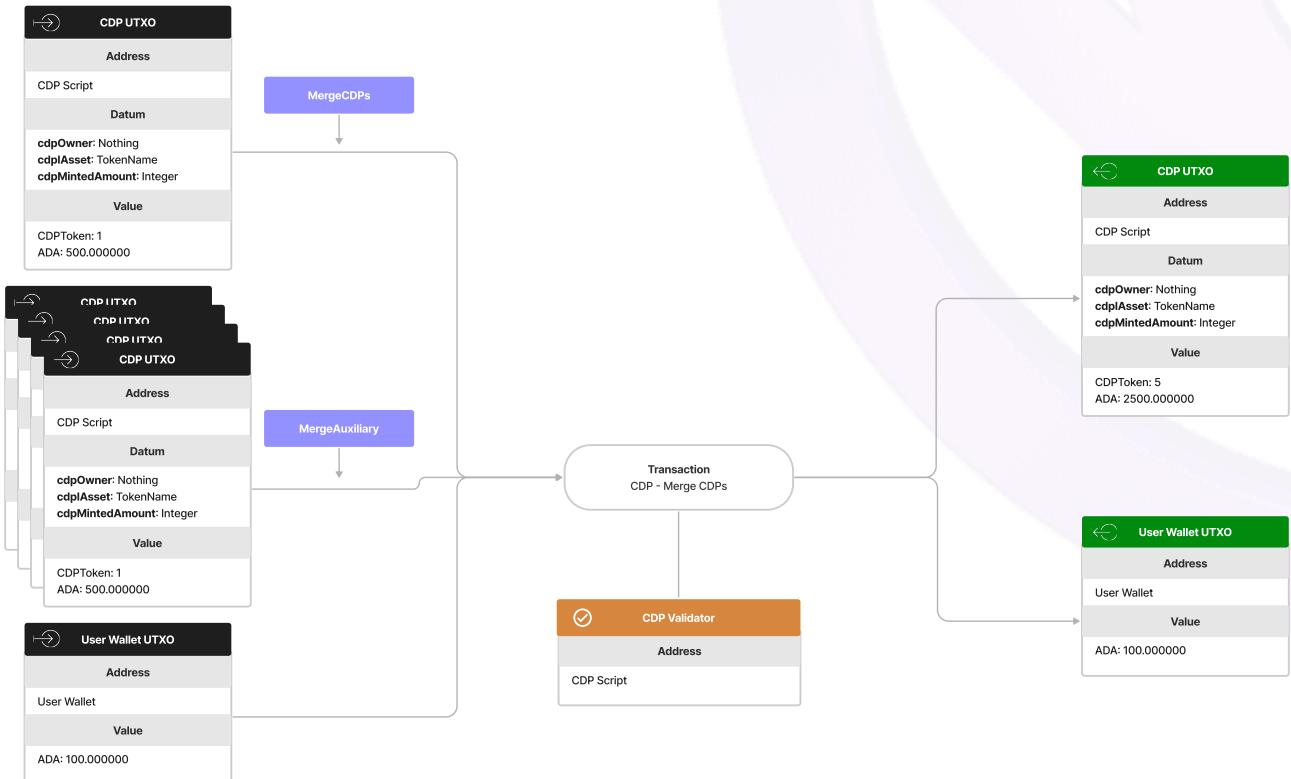

Figure 29: Example of 5 CDPs being merged together

Table 20: Stability Pool outputs

Type	Description	Datum	Values
StabilityPool	Each StabilityPool output holds iAssets to be used for liquidations	<p><i>spIAsset</i>: The name of the iAsset that this SP is for</p> <p><i>spSnapshot</i>: The snapshot of funds for the SP. See Snapshot</p> <p><i>epochToScaleToSum</i>: A map of the sum of funds for a particular epoch and scale</p>	<p><i>StabilityPoolToken</i>: 1</p> <p><i>iAsset</i>: Funded by stability providers</p> <p><i>ADA</i>: Collateral transferred to SP from liquidated CDPs</p>
EpochToScaleToSum	Archives EpochToScaleToSum records	<p><i>sessSnapshot</i>: A snapshot of EpochToScaleToSum</p> <p><i>sessAsset</i>: The name of the iAsset that this snapshot is for</p>	<i>SnapshotToken</i> : 1
Account	Each Account output holds a range of iAsset flavors	<p><i>accOwner</i>: The owner of the SP Account</p> <p><i>accIAsset</i>: The name of the iAsset that this SP Account is for</p> <p><i>accSnapshot</i>: The snapshot of funds from the SP at the time of deposit</p>	<i>AccountToken</i> : 1

3.2.2 SP Endpoints

SP: Create Account Creates an account with a SP the first time a user deposits iAsset

Type	Amount	Description
Redeemer	N.A.	CreateAccount, takes as a parameter a public key hash corresponding to a user's wallet and an amount of iAsset to stake
Consume	1	SP UTXO representing the global state for the iAsset type being deposited
Mint	1	Account Token representing the user's SP position
Output	1	SP UTXO with the updated global state
Output	1	Account UTXO holding the user's Account Token

SP: Add iAsset Adds more iAsset to user's SP account

Type	Amount	Description
Redeemer	N.A.	AdjustAccount, takes as a parameter an amount of iAsset
Redeemer	N.A.	SpendAccount
Consume	1	SP UTXO representing the global state
Consume	1	Account UTXO representing the user's Stability Pool account to be adjusted
Consume	1+	UTXOs containing the user's iAsset to be deposited into their SP account
Output	1	SP UTXO with the updated global state
Output	1	Account UTXO representing the user's updated SP account

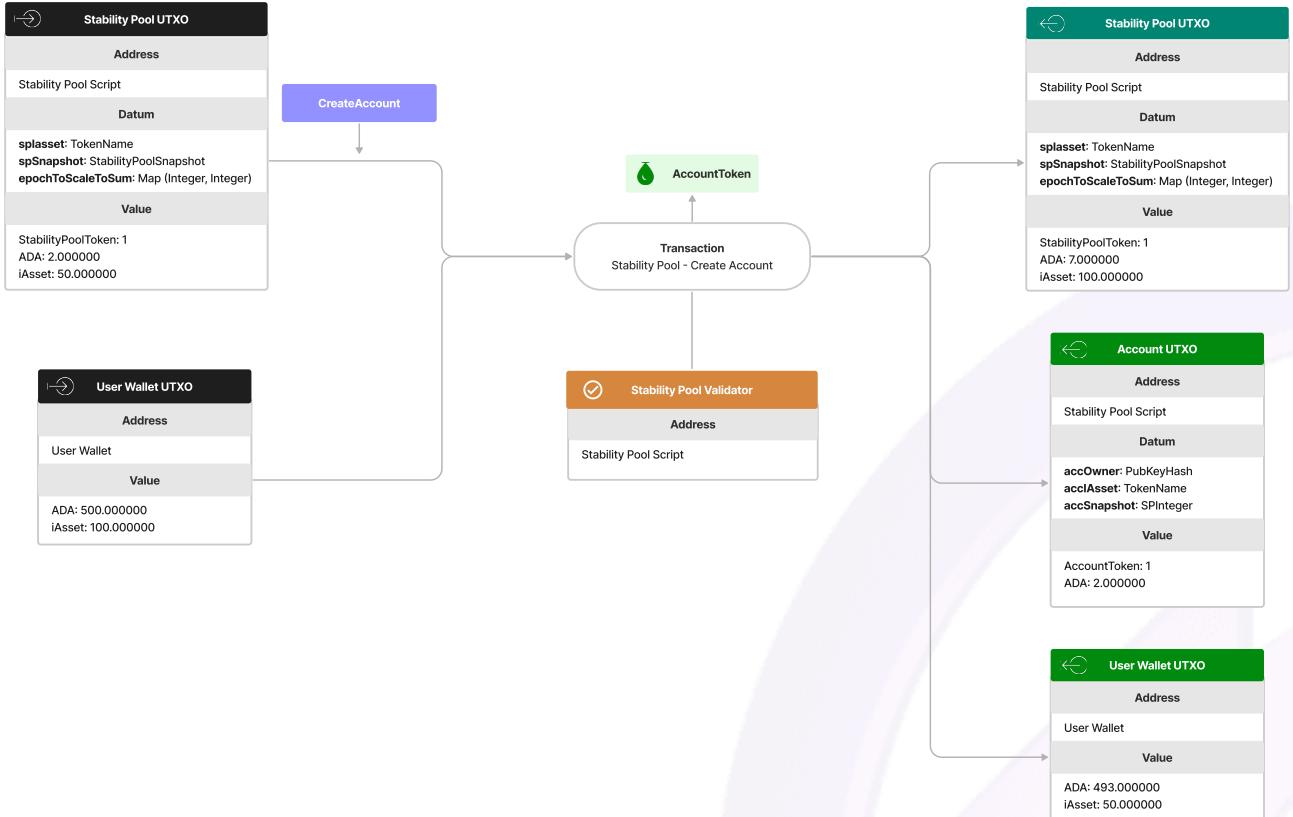

Figure 30: Example of a user making their first deposit into a Stability Pool, depositing 50 iAsset, 2 ADA, and paying a 5 ADA fee

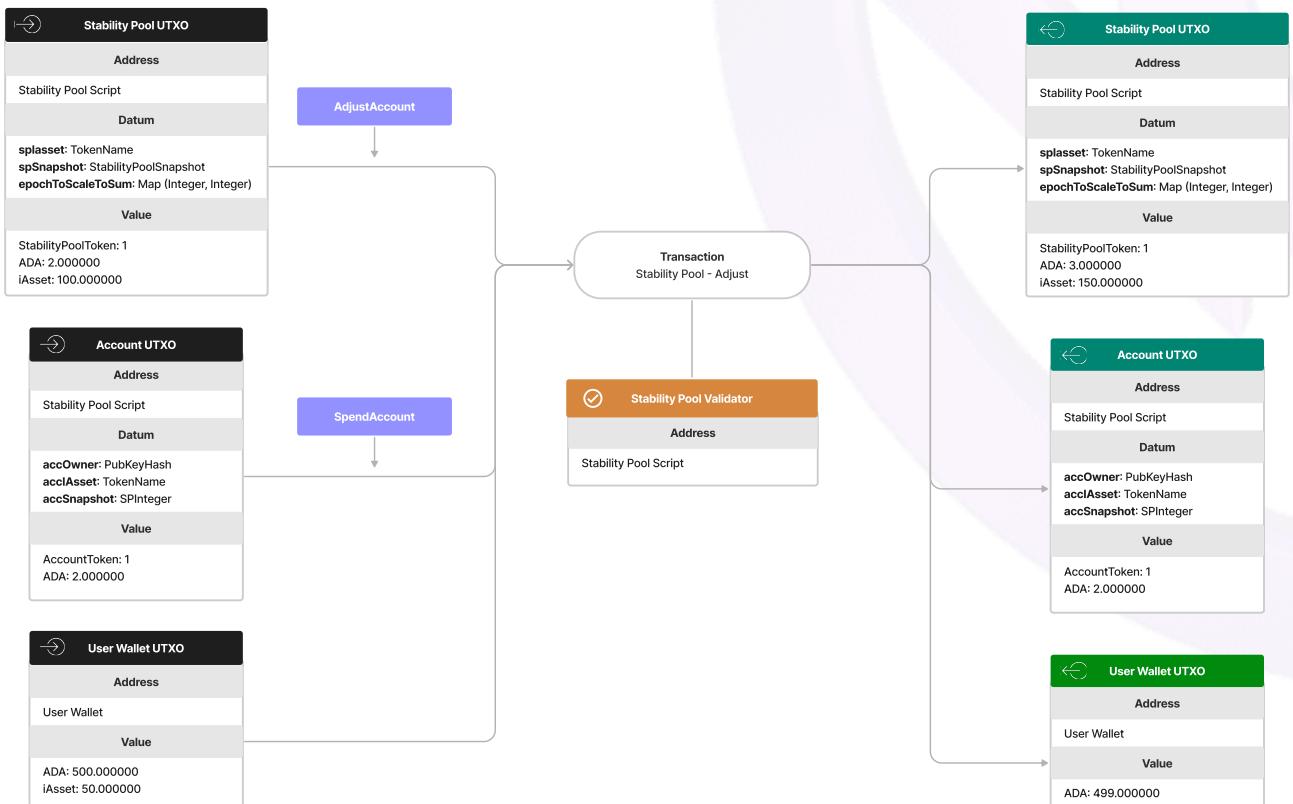

Figure 31: Example of a user depositing 50 iAsset into the Stability Pool, paying a 1 ADA fee

SP: Close Account Closes a user's SP account

Type	Amount	Description
Redeemer	N.A.	Close
Redeemer	N.A.	SpendAccount
Consume	1	Stability Pool UTXO representing the global state
Consume	1	Account UTXO representing the user's Stability Pool account to be closed
Burn	1	Account Token representing the user's former Stability Pool account
Output	1	Stability Pool UTXO with the updated global state
Output	1	UTXO containing the iAsset that was deposited in the Stability Pool account

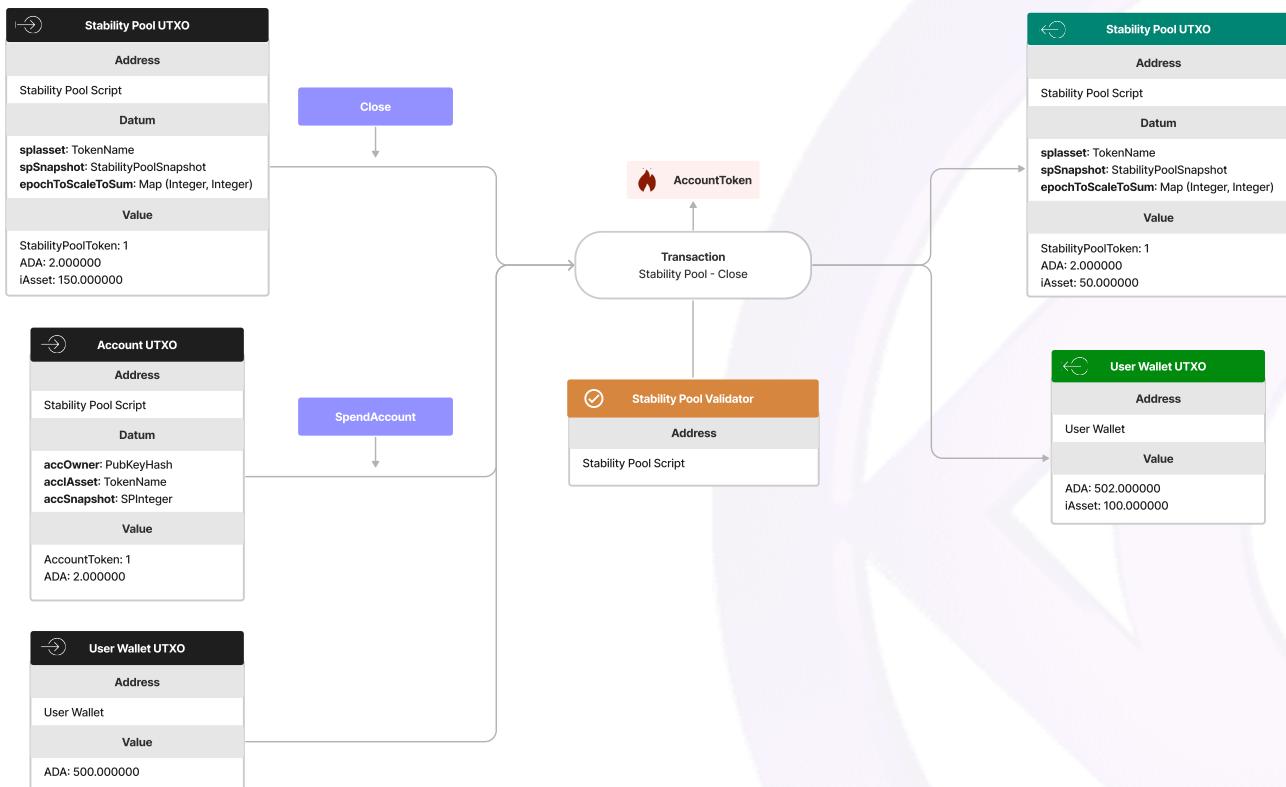

Figure 32: Example of a user withdrawing 100 iAsset from the Stability Pool

Stability Pool: RecordEpochToScaleToSum Archives EpochToScaleToSum records

Type	Amount	Description
Redeemer	N.A.	RecordEpochToScaleToSum
Consume	1	SP UTXO representing the global state
Consume	1	Account UTXO representing the user's Stability Pool account to be closed
Burn	1	Account Token representing the user's former SP account
Output	1	SP UTXO with the updated global state
Output	1	UTXO containing the iAsset that was deposited in the SP account

3.3 Staking

The Staking contract is used primarily by the Indigo DAO Governance package for proving the ownership of INDY tokens and locking those tokens upon voting. The Staking contract also includes functionality to collect protocol fees from Collector UTXOs.

Table 25: Staking native tokens

Name	Description	Minting Policy
StakingManagerNFT	The NFT identifies the authentic StakingManager output The NFT must be stored in the StakingManager output Validator scripts ensure that this NFT always stays at the StakingManager output	The protocol mints exactly 1 token, before launch
StakingToken	Identify the authentic StakingPosition output	The transaction must consume a StakingManagerNFT or a StakingToken

3.3.1 Parameters

- `stakingManagerNFT :: StakingManagerNFT`. NFT of StakingManager.
- `stakingToken :: StakingToken`. Token for identifying authentic Staking Position output.
- `indyToken :: INDY`.
- `pollToken :: PollToken`. Token identifying authentic Poll output.
- `versionRecordToken :: VersionRecordToken`. Token identifying the VersionRegistry output.
- `collectorValHash :: ValidatorHash`. The collector script, used as a bridge between Staking and Poll Script.
- `cdpToken :: CDPToken`. Necessary for OffChain Endpoint to construct CollectorScriptParams.

Table 26: Staking outputs

Type	Description	Datum	Values
StakingManager	Only one output of this type is stored in the script To create a StakingPosition output, the user must consume this output in the transaction	<i>totalStake</i> : The total amount of staked INDY <i>mSnapshot</i> : The snapshot of ADA rewards for INDY stakers	<i>StakingManagerNFT</i> : 1
StakingPosition	An individual user's INDY staking position	<i>owner</i> : The owner of the staking position <i>lockedAmount</i> : A map of Poll ID to (Vote Amount, Proposal End Time) <i>pSnapshot</i> : The snapshot of ADA rewards for the INDY staker	<i>StakingToken</i> : 1

3.3.2 Staking Endpoints

Staking: Create Creates a user's staking position

Type	Amount	Description
Redeemer	N.A.	CreateStakingPosition
Consume	1	Staking Manager UTXO representing the global state of staking positions
Consume	1+	UTXOs containing the user's INDY to be staked

Type	Amount	Description
Mint	1	Staking Token representing the user's staking position
Output	1	Staking Manager UTXO with the updated global state
Output	1	Staking Position UTXO holding the user's Staking Token

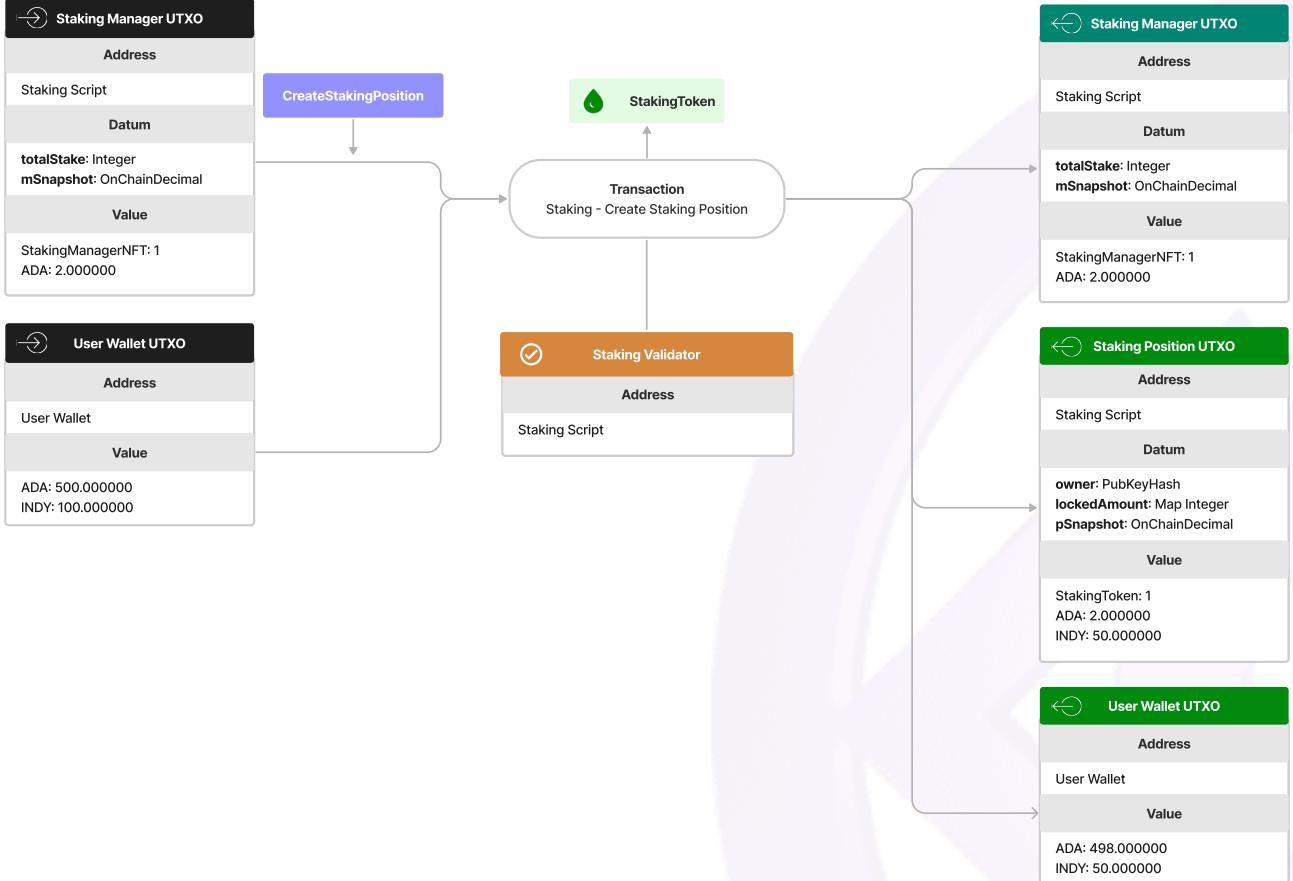

Figure 33: Example of a user staking INDY for the first time, depositing 50 INDY

Staking: Unstake Unstakes a user's staking position

Type	Amount	Description
Redeemer	N.A.	UpdateTotalStake
Redeemer	N.A.	Unstake
Consume	1	Staking Manager UTXO representing the global state of staking positions
Consume	1	Staking Position UTXO representing the user's staking position
Burn	1	Staking Token representing the user's former staking position
Output	1	Staking Manager UTXO with the updated global state
Output	1	UTXOs containing the user's previously staked INDY

Staking: Stake Adds more INDY to a user's staking position

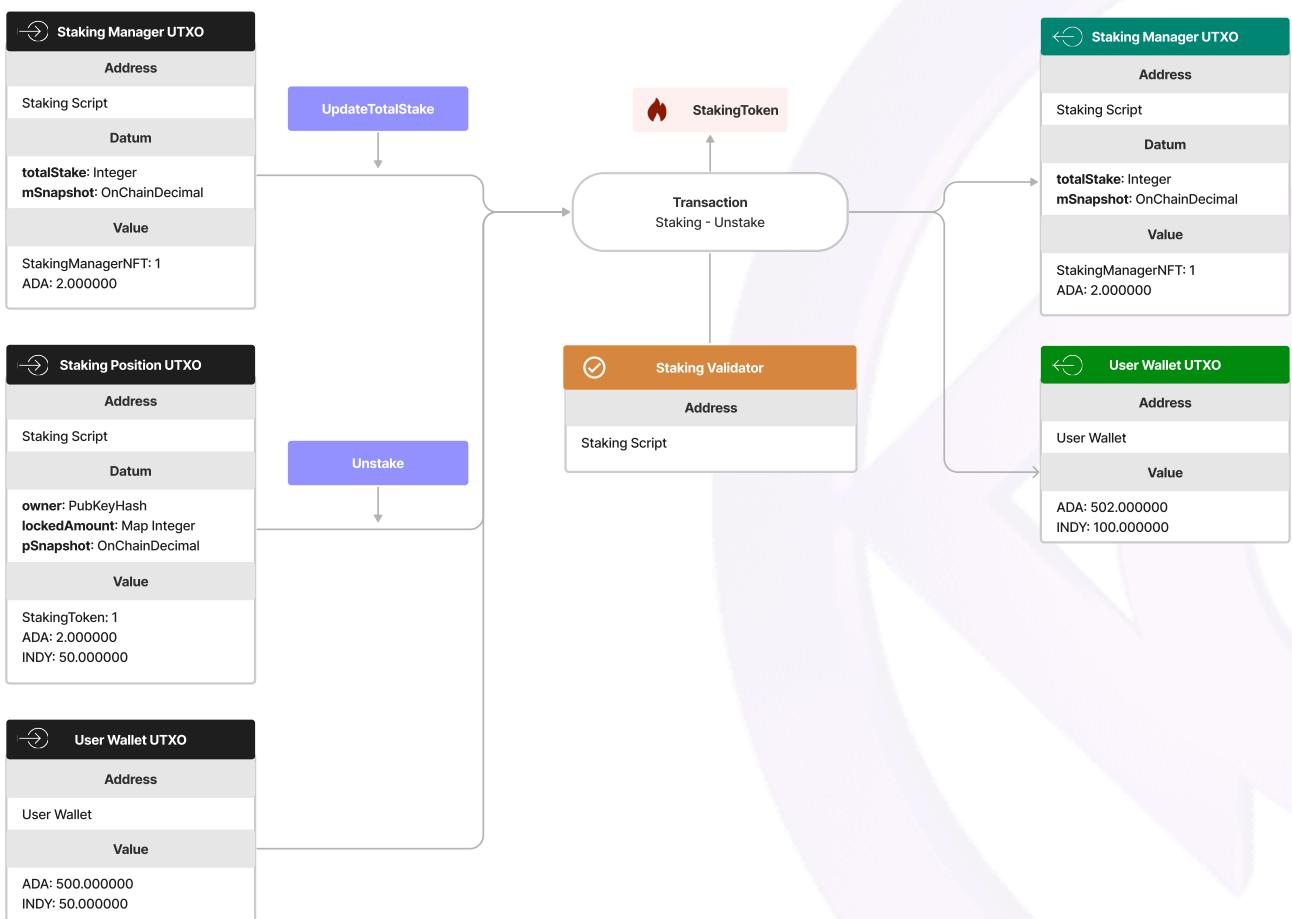

Figure 34: Example of a user unstaking 50 INDY

Type	Amount	Description
Redeemer	N.A.	UpdateTotalStake
Redeemer	N.A.	AdjustStakedAmount
Consume	1	Staking Manager UTXO representing the global state of staking positions
Consume	1	Staking Position UTXO representing the user's staking position
Consume	1+	UTXOs containing the INDY to be staked
Output	1	Staking Manager UTXO with the updated global state
Output	1	Staking Position UTXO representing the user's updated staking position

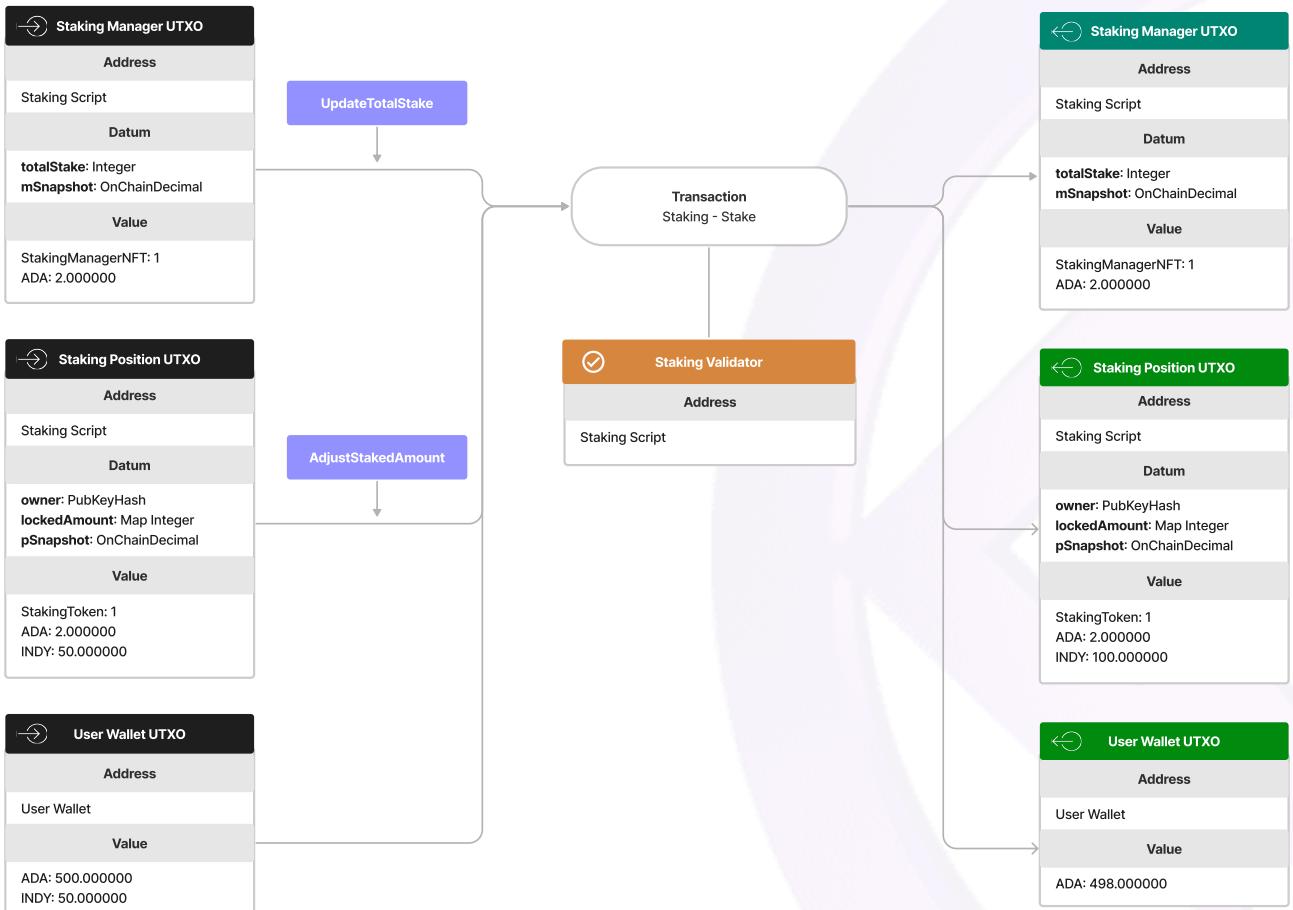

Figure 35: Example of a user staking an additional 50 INDY

Staking: Distribute Distributes fees from the Collector to the Staking Manager

Type	Amount	Description
Redeemer	N.A.	Distribute
Redeemer	N.A.	Collect
Consume	1	Staking Manager UTXO representing the global state of staking positions
Consume	1+	Collector UTXOs containing the fees to distribute
Output	1	Staking Manager UTXO with the updated global state

Staking: Withdraw Rewards Withdraw ADA rewards allocated to a user's staking position

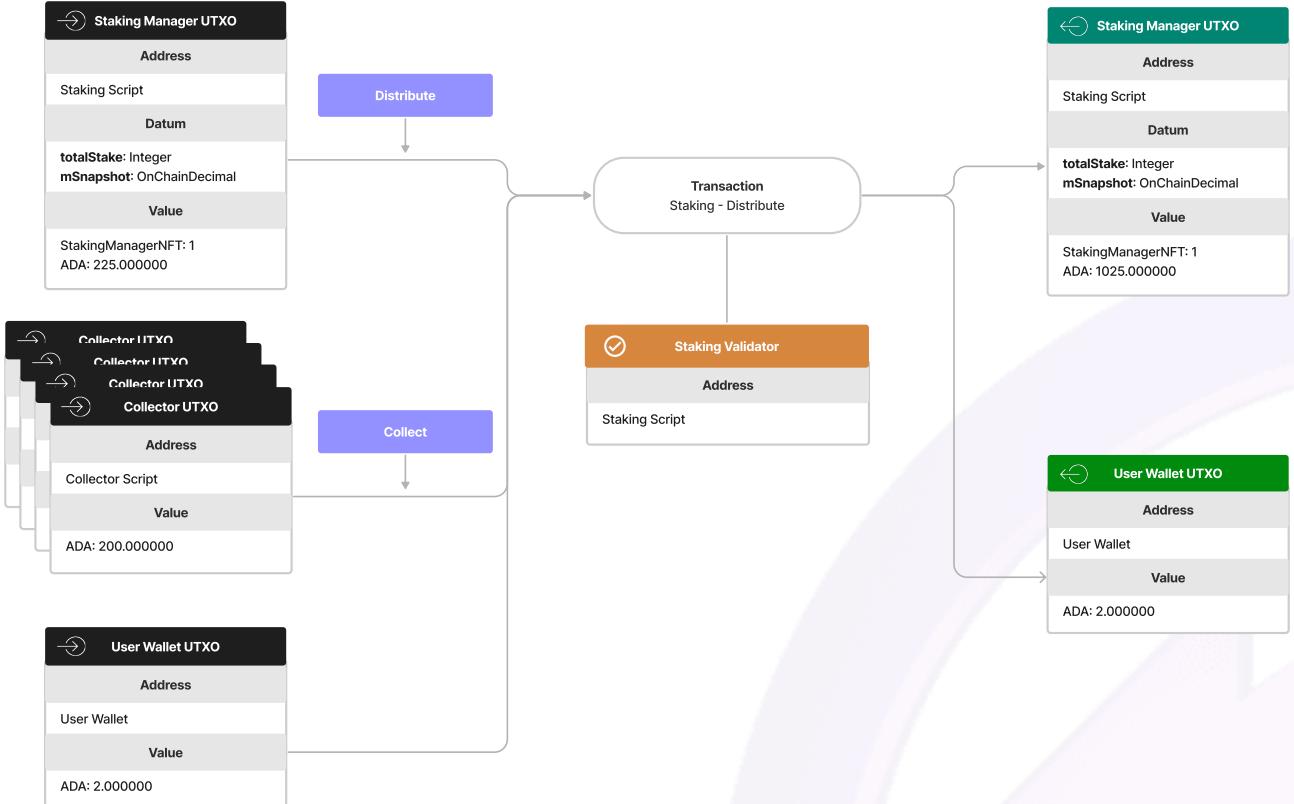

Figure 36: Example of fees from the Collector being distributed to the Staking Manager

Type	Amount	Description
Redeemer	N.A.	UpdateTotalStake
Redeemer	N.A.	AdjustStakedAmount
Consume	1	Staking Manager UTXO representing the global state of staking positions
Consume	1	Staking Position UTXO representing the user's staking position
Output	1	Staking Manager UTXO with the updated global state
Output	1	Staking Position UTXO representing the user's staking position

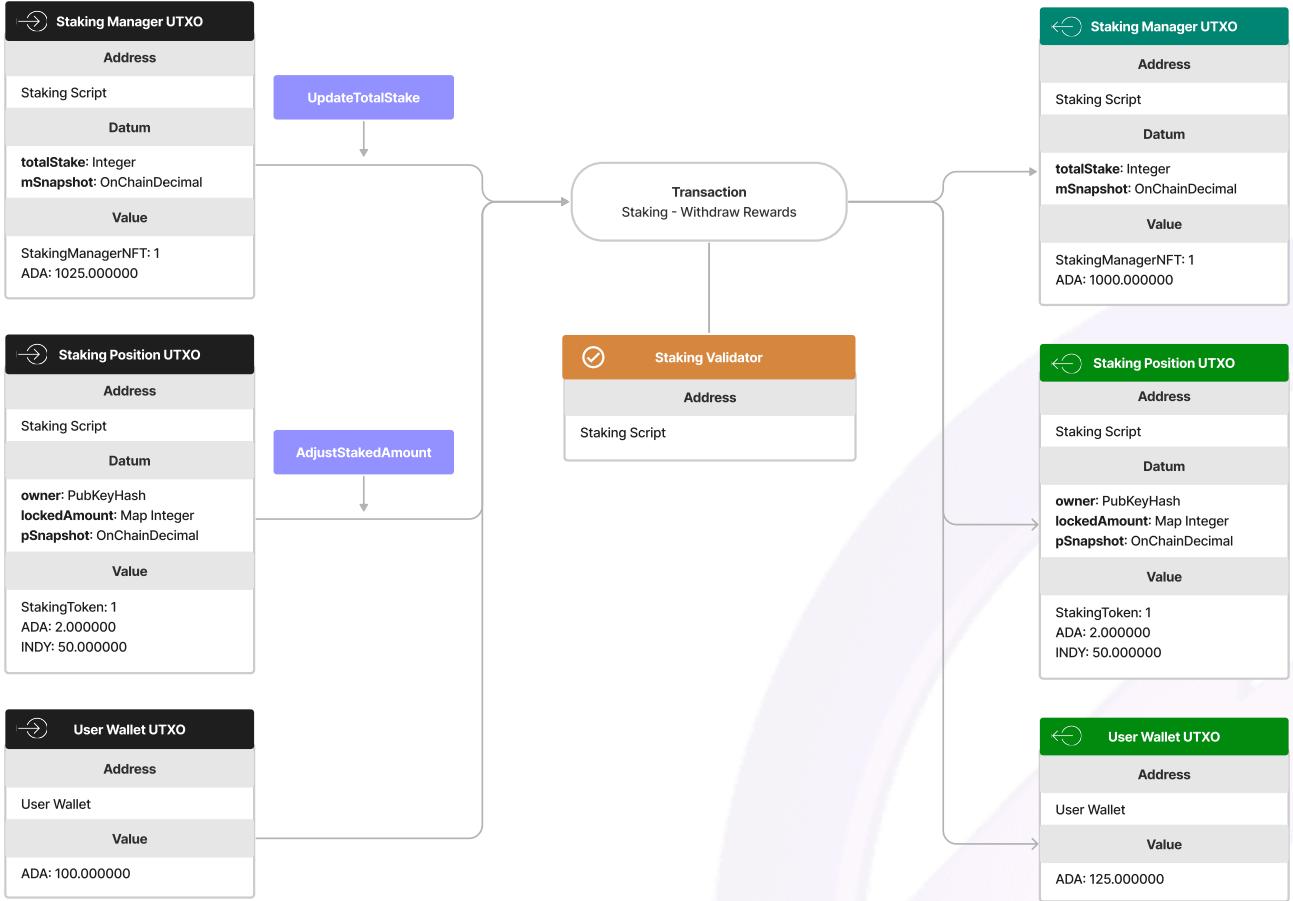

Figure 37: Example of a user withdrawing a 25 ADA reward

Staking: Unlock Unlock staked INDY from a user's position to make those INDY withdrawable

Type	Amount	Description
Redeemer	N.A.	Unlock
Consume	1	Staking Manager UTXO representing the global state of staking positions
Consume	1	Staking Position UTXO representing the user's staking position
Output	1	Staking Manager UTXO with the updated global state
Output	1	Staking Position UTXO representing the user's staking position

3.4 Governance

Governance is a group of several contracts: Gov, Poll, Execute, and VersionRegistry. The Gov contract stores protocol parameters and controls the creation/ending of a Governance Poll. The Poll contract handles the creation of vote shards, voting, merging of vote shards, AQB calculations, and the ending of a Poll. The Execute contract takes the result of a passed proposal and applies the appropriate action to the contracts. The VersionRegistry contract handles the creation of Version Records, which can be used by other protocol scripts to find an upgrade path.

Table 33: Governance native tokens

Name	Description	Minting Policy
GovNFT	Identify authentic Governance output Governance script ensures that this NFT always stays at the Governance output	The protocol mints exactly 1 token at initialization
PollToken	Identifies an authentic proposal Validator scripts ensure that this token always stays at Poll output	The transaction must consume GovNFT
UpgradeToken	Identifies a passed proposal and the upgrade contract Validator scripts ensure that this token always stays at Execute output	The transaction must consume a PollToken
VersionRecordToken	Identifies a potential upgrade path for a contract Validator scripts ensure that this token always stays at VersionRegistry output	The transaction must consume UpgradeToken

3.4.1 Execute Script Parameters

- `govNFT` :: `GovNFT`. NFT for identifying authentic Governance Script output.
- `upgradeToken` :: `UpgradeToken`. The asset class for identifying a valid upgrade token.
- `iAssetToken` :: `iAssetToken`. Token for identifying authentic iAsset output.
- `stabilityPoolToken` :: `StabilityPoolToken`. Token for identifying authentic SP output.
- `versionRecordToken` :: `VersionRecordToken`. Token for identifying the version record for a protocol upgrade.
- `cdpValHash` :: `ValidatorHash`. Hash of CDP script, used for verifying the output of a CDP.
- `sPoolValHash` :: `ValidatorHash`. Hash of SP script, used for verifying the output of a SP.
- `versionRegistryValHash` :: `ValidatorHash`. Hash of Version Registry script, used for verifying the output of a Version Registry.

3.4.2 Gov Script Parameters

- `govNFT` :: `GovNFT`. NFT for identifying authentic Governance Script output.
- `pollToken` :: `PollToken`. The asset class for identifying a valid Poll token.
- `upgradeToken` :: `UpgradeToken`. The asset class for identifying a valid Upgrade token.
- `indyAsset` :: `INDY`.
- `versionRecordToken` :: `VersionRecordToken`. Token for identifying the version record for a protocol upgrade.
- `pollManagerValHash` :: `ValidatorHash`. Hash of Poll Manager script, used for verifying the output of a Poll.
- `gBiasTime` :: `POSIXTime`. Used to apply some leverage to the voting procedures.

3.4.3 Poll Manager Script Parameters

- `govNFT` :: `GovNFT`. NFT for identifying authentic Governance Script output.
- `stakingManagerNFT` :: `StakingManagerNFT`. NFT for identifying authentic Staking Manager output.
- `pollToken` :: `PollToken`. The asset class for identifying a valid Poll token.

- `upgradeToken` :: `UpgradeToken`. The asset class for identifying a valid Upgrade token.
- `stakingToken` :: `StakingToken`. The asset class for identifying a valid Staking Position token.
- `indyAsset` :: `INDY`.
- `govExecuteValHash` :: `ValidatorHash`. Hash of Execute script, used for verifying the output of a Upgrade token.
- `stakingValHash` :: `ValidatorHash`. Hash of Staking script, used for verifying the output of the Staking token.
- `pBiasTime` :: `POSIXTime`. Used to apply some leverage to the voting procedures.
- `treasuryValHash` :: `ValidatorHash`. Hash of the treasury script.
- `initialIndyDistribution` :: `Integer`. Used by the electorate calculation for the ITD value.
- `totalINDYSupply` :: `Integer`. Used by the electorate calculation for the t value.
- `distributionSchedule` :: `DistributionSchedule`. Used by the electorate calculation to map all the distributions and their intended distribution rates.
- `shardsAddress` :: `Address`. Poll shard validator address.

3.4.4 Poll Shard Script Parameters

- `pollToken` :: `PollToken`. The asset class for identifying a valid Poll token.
- `stakingToken` :: `StakingToken`. The asset class for identifying a valid Staking Position token.
- `indyAsset` :: `INDY`.
- `stakingValHash` :: `ValidatorHash`. Hash of Staking script, used for verifying the output of the Staking token.

3.4.5 Version Record Script Parameters

- `upgradeToken` :: `UpgradeToken`. The asset class for identifying a valid Upgrade token.

Table 34: Governance outputs

Type	Description	Datum	Values
Governance	Only one output of this type is stored in the script To create a Poll output, the user must consume this output in the transaction To store the protocol parameters	<i>currentProposal</i> : The number of opened proposals <i>protocolParams</i> : The parameters of the protocol <i>currentVersion</i> : The current version of the protocol, starting at 0 <i>protocolStartTime</i> : The time that the protocol starts	<i>GovNFT</i> : 1

Table 34: Governance outputs

Type	Description	Datum	Values
Poll Manager	The Poll Manager acts as a central UTXO that manages the content of the poll	<p><i>pId</i>: The identifying key for this particular proposal</p> <p><i>pOwner</i>: The pub key hash of the owner of the poll</p> <p><i>pContent</i>: The intended action of this poll: ProposeAsset, MigrateAsset, ModifyProtocolParams, UpgradeProtocol, and TextProposal</p> <p><i>pStatus</i>: The count of yes and no votes</p> <p><i>pEndTime</i>: The time in which the poll should be ended</p> <p><i>pCreatedShards</i>: The number of shards created</p> <p><i>pTalliedShards</i>: The number of shards tallied and merged into Poll Manager</p> <p><i>pTotalShards</i>: The number of shards in total</p> <p><i>pProposeEndTime</i>: The time in which all of the poll shards must be created within</p> <p><i>pExpirationTime</i>: The time in which the poll should expire</p> <p><i>pProtocolVersion</i>: The protocol version at the time the poll UTXO was created</p>	<i>PollToken</i> : 1
Poll Shard	A derivation of the Poll Manager that stores some votes	<p><i>psId</i>: The identifying key for this particular proposal</p> <p><i>psStatus</i>: The count of yes and no votes</p> <p><i>psEndTime</i>: The time in which the poll should be ended</p> <p><i>psManagerAddress</i>: The address of the poll manager script</p>	<i>PollToken</i> : 1

Table 34: Governance outputs

Type	Description	Datum	Values
Upgrade	This output can be consumed to process a passed proposal	<p><i>uId</i>: The identifying key for the passed proposal this upgrade was derived from</p> <p><i>uContent</i>: The intended action of this upgrade: ProposeAsset, MigrateAsset, ModifyProtocolParams, UpgradeProtocol, and TextProposal</p> <p><i>uPassedTime</i>: The time in which the poll was passed</p> <p><i>uEndTime</i>: The time in which the upgrade should be deemed "expired"</p> <p><i>uProtocolVersion</i>: The protocol version at the time the upgrade UTXO was created</p>	<i>UpgradeToken</i> : 1
VersionRecord	Given a particular version id, the path for upgrading to a new validator	<p><i>versionId</i>: The version that the record is associated with. Version starts at 0 at genesis and works up</p> <p><i>versionPaths</i>: A map of the validator name that should be upgraded and the currency symbol that can be used to process the upgrade</p>	<i>VersionRecordToken</i> : 1

3.4.6 Governance Endpoints

Governance: Create Proposal Creates a proposal to enact changes

Type	Amount	Description
Redeemer	N.A.	CreatePoll, takes as parameters the time the poll voting period should end, a public key hash corresponding to a user's wallet, and the Poll's type (e.g.: ProposeAsset, MigrateAsset, etc.)
Consume	1	Governance UTXO
Consume	1+	INDY to be deposited to create the proposal
Mint	1	Poll Token representing the newly created proposal
Output	1	Governance UTXO
Output	1	Poll Manager UTXO that represents the proposal

Governance: Vote Vote on an open proposal

Type	Amount	Description
Redeemer	N.A.	Vote, takes as a parameter the vote choice (yes or no)
Redeemer	N.A.	Lock
Consume	1	Poll Shard UTXO to cast the vote with
Consume	1	Staking Position UTXO representing the user's voting power

Type	Amount	Description
Output	1	Poll Shard UTXO with the vote recorded
Output	1	Staking Position UTXO representing the user's voting power

Governance: Create Shards Create one or more shards to allow users to vote on proposals

Type	Amount	Description
Redeemer	N.A.	CreateShards, takes as a parameter the time the poll voting period should end
Consume	1	Poll Manager UTXO that represents the proposal
Output	∞	Poll Shard UTXOs to record votes

Governance: Merge Shards Merges one or more shards so that votes can be tallied

Type	Amount	Description
Redeemer	N.A.	MergeShardsManager, takes as a parameter the time the poll voting period should end
Redeemer	N.A.	MergeShards
Consume	1	Poll Manager UTXO that represents the proposal
Consume	∞	Poll Shard UTXOs to merge
Output	1	Poll Manager UTXO with the updated vote count

Governance: End Proposal Passed End a proposal that has passed

Type	Amount	Description
Redeemer	N.A.	EndPoll, takes as a parameter the time the poll voting period should end
Consume	1	Poll Manager UTXO that represents the proposal
Reference	1	Governance UTXO
Mint	1	Upgrade Token
Burn	1	Poll Token
Output	1	Upgrade UTXO

Governance: End Proposal (Failed or Expired) End a proposal that has failed or expired

Type	Amount	Description
Redeemer	N.A.	EndPoll, takes as a parameter the time the poll voting period should end
Consume	1	Poll Manager UTXO that represents the proposal
Reference	1	Governance UTXO
Burn	1	Poll Token
Output	1	Treasury UTXO containing the INDY deposited when the proposal was created

Governance: Execute Text Proposal Execute a passed proposal containing text adopted by the DAO

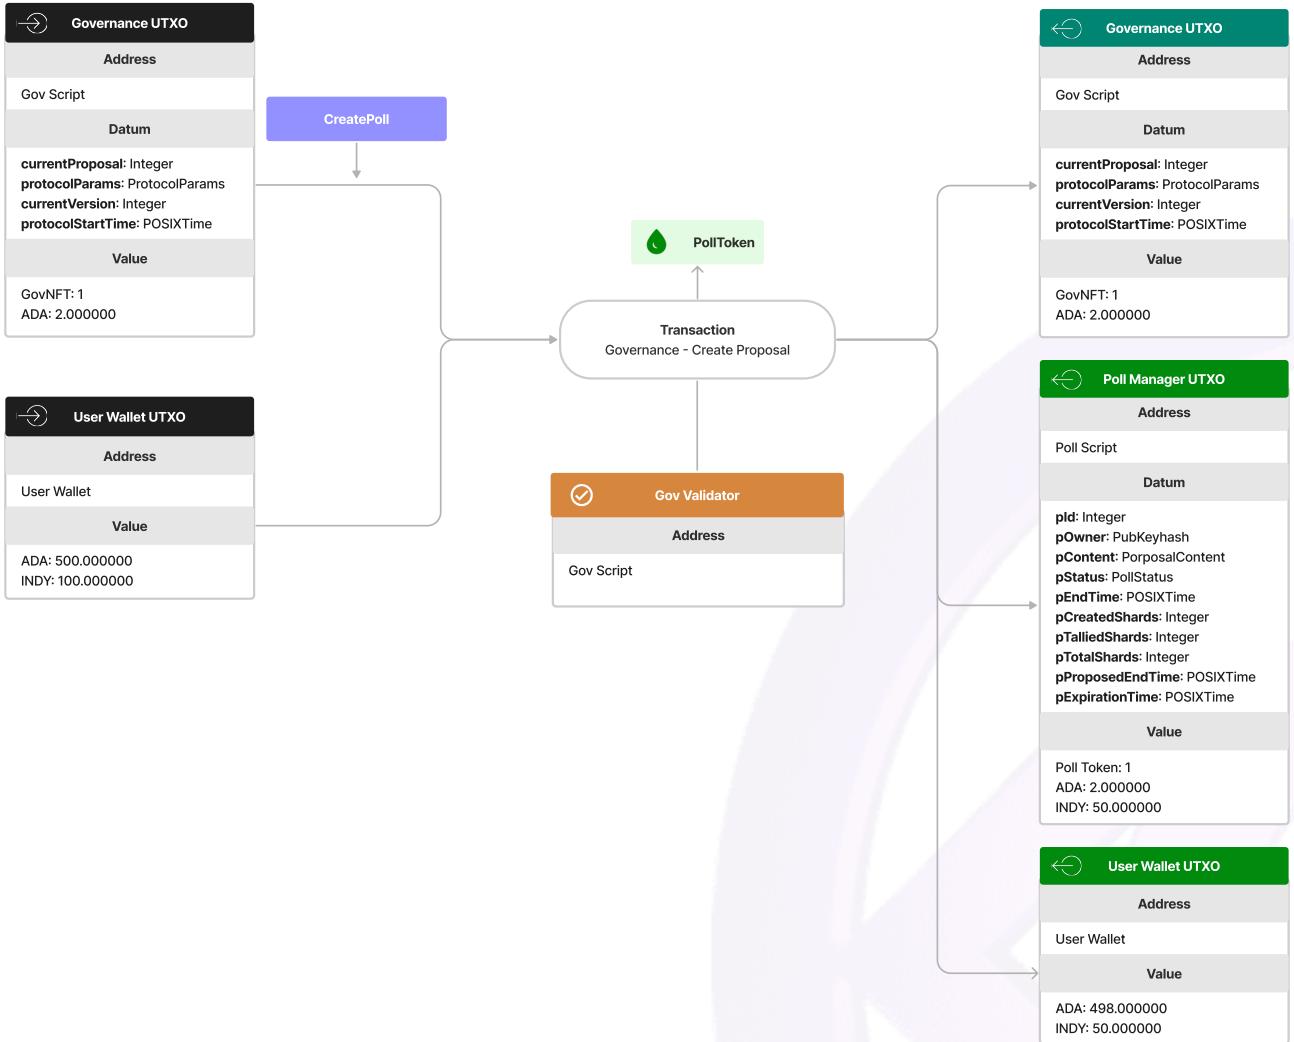

Figure 38: Example of a user depositing 50 INDY and 2 ADA to create a proposal

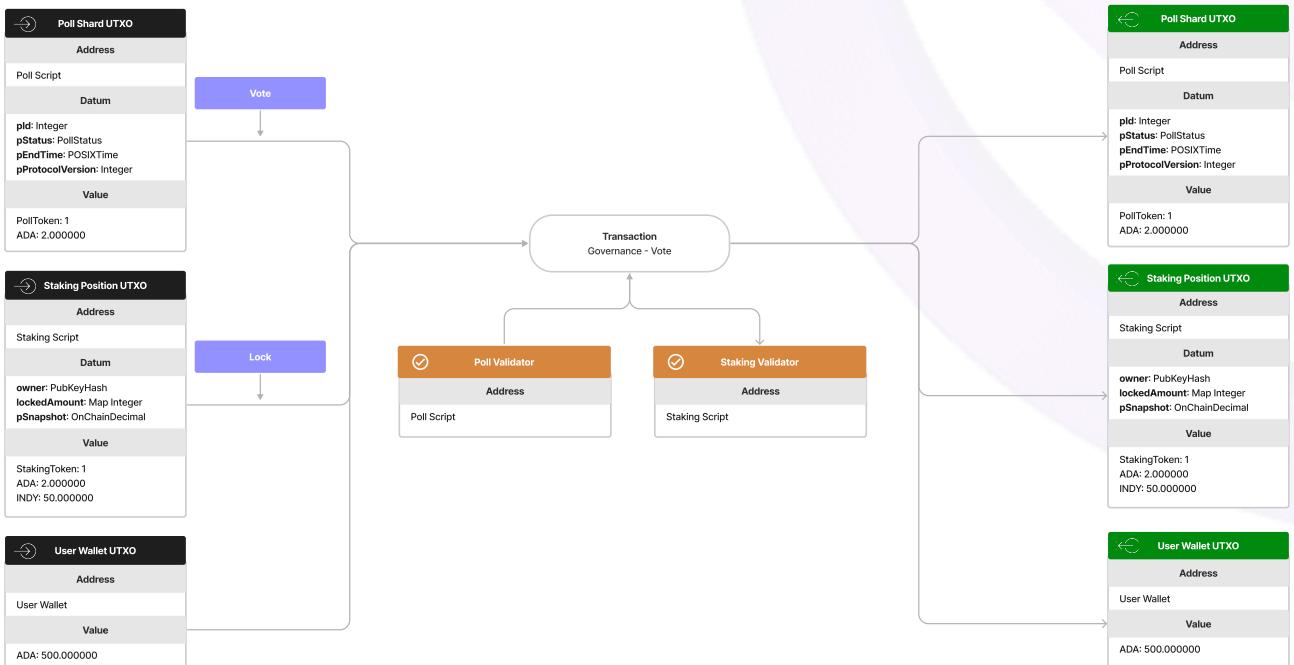

Figure 39: Example of a user casting their vote

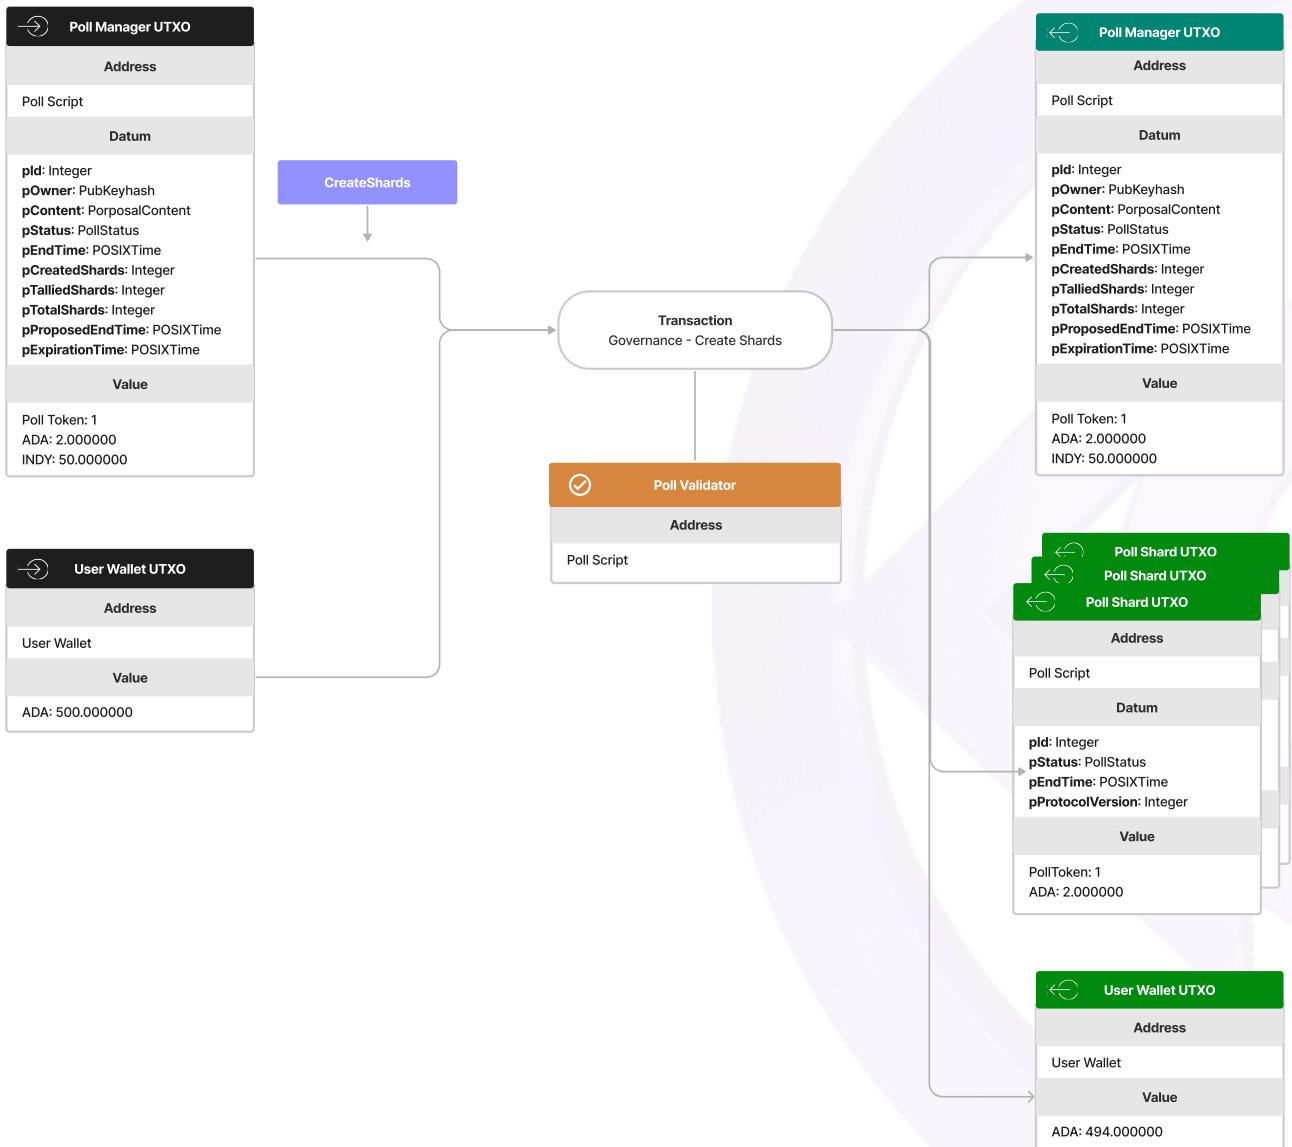

Figure 40: Example of a user creating three vote shards for their proposal and depositing a refundable 6 ADA

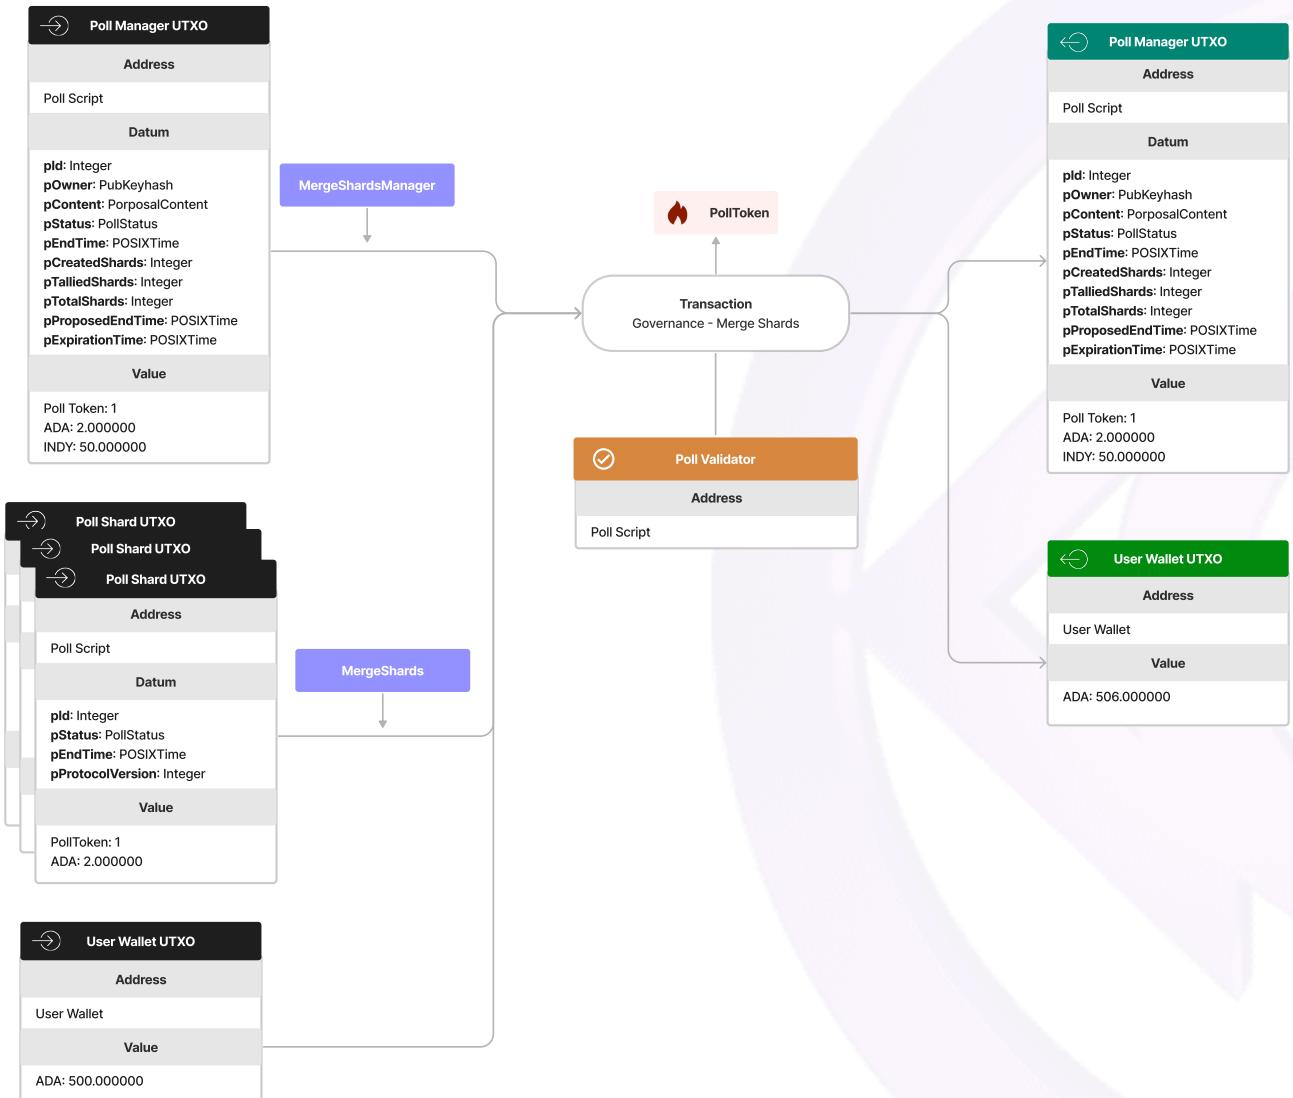

Figure 41: Example of a user merging three vote shards for their proposal and retrieving their original 6 ADA deposit

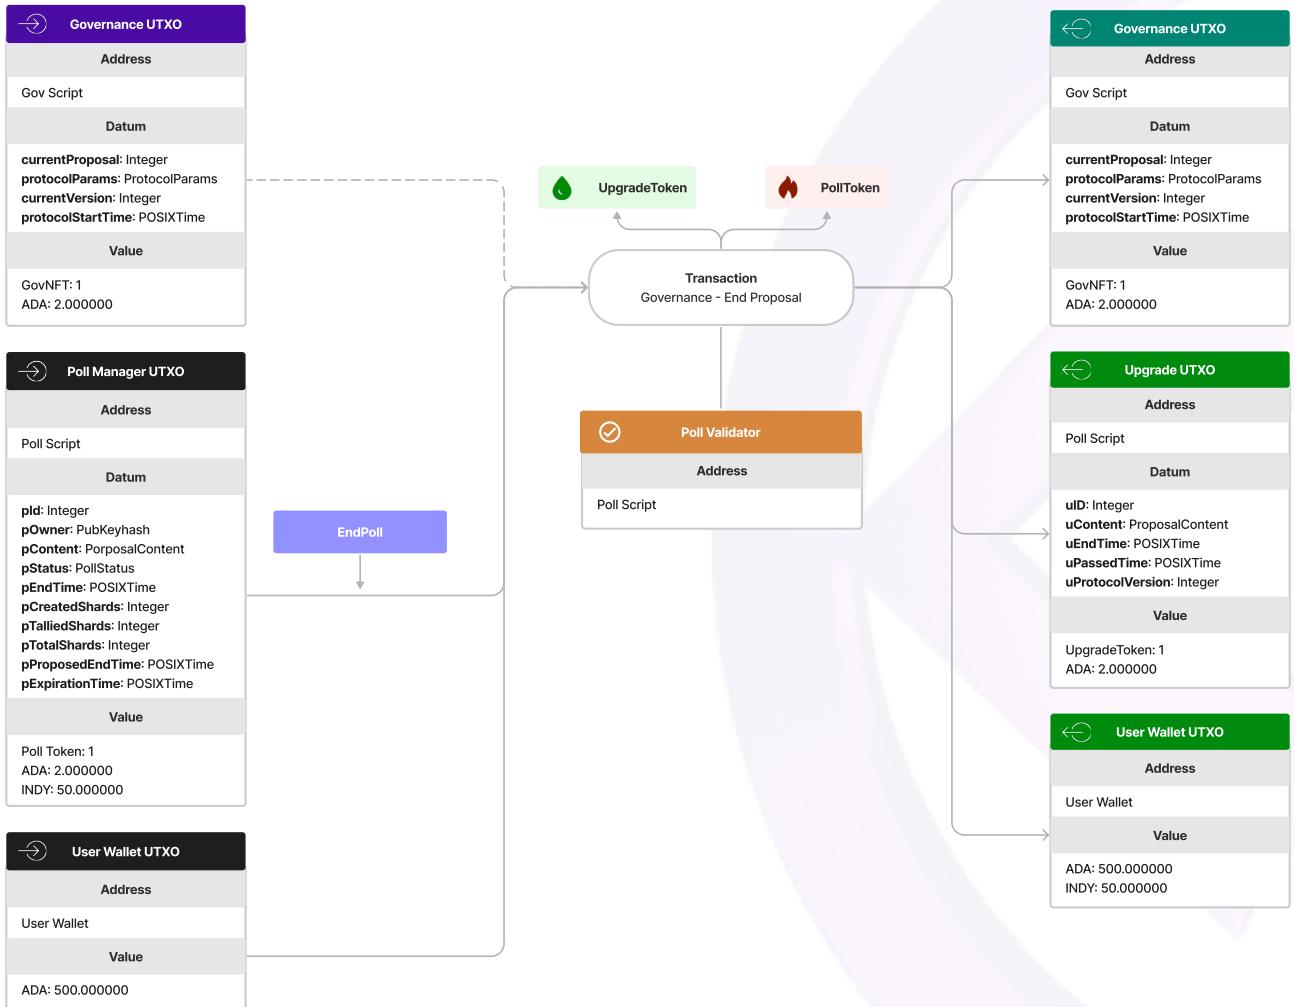

Figure 42: Example of a user ending their proposal that passed and retrieving their original 50 INDY deposit

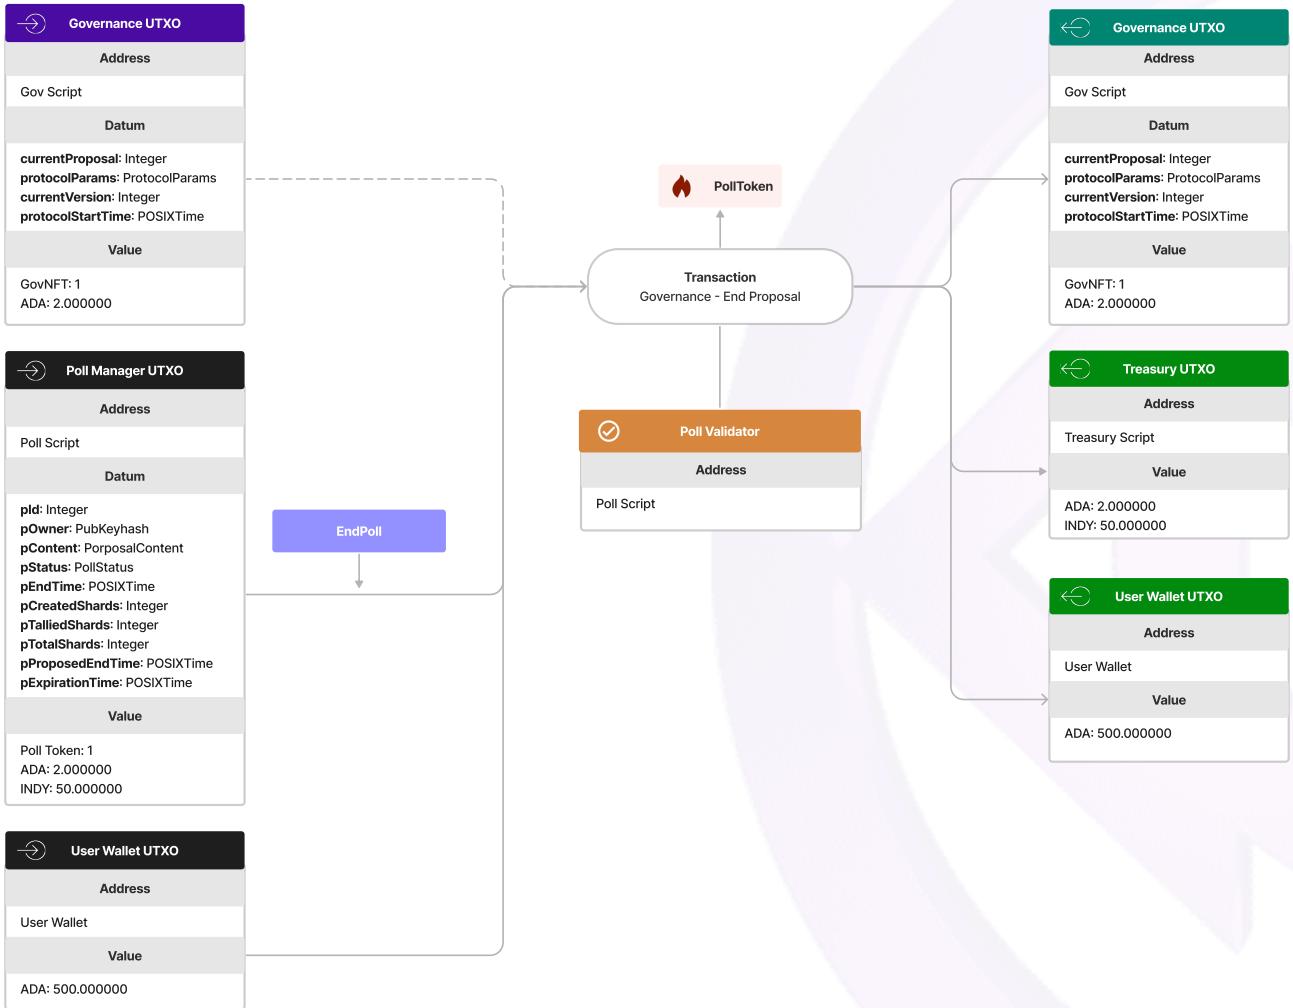

Figure 43: Example of a user ending a failed or expired proposal and sending the deposited 50 INDY to the Treasury

Type	Amount	Description
Redeemer	N.A.	EndPoll, takes as a parameter the time the poll voting period should end
Redeemer	N.A.	Execute
Consume	1	Upgrade UTXO containing the Upgrade Token for the passed proposal
Burn	1	Upgrade Token

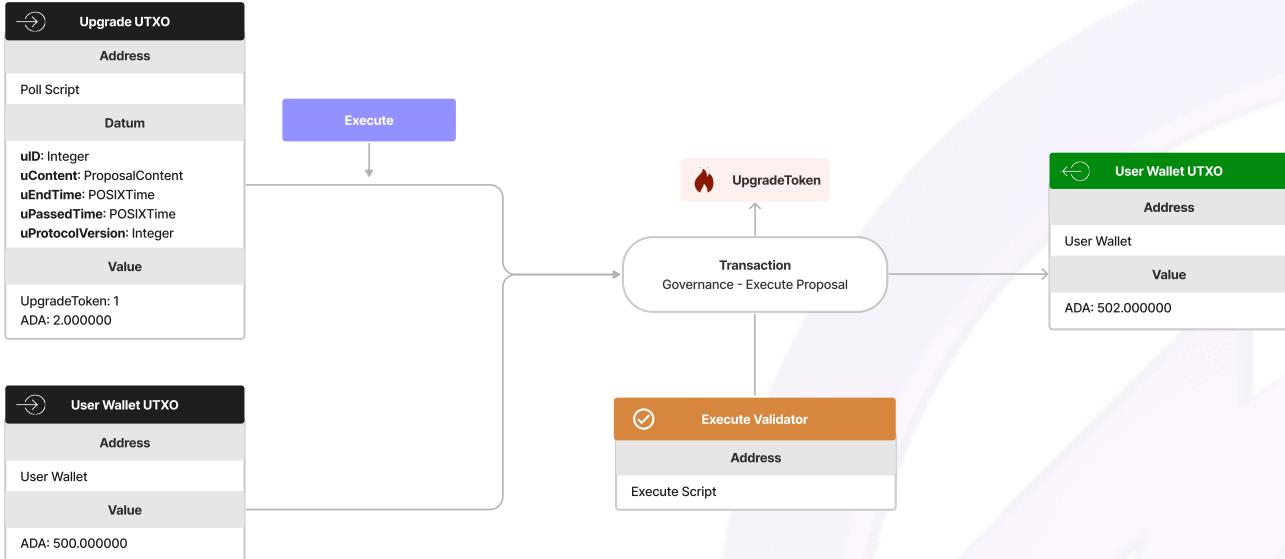

Figure 44: Example of a user executing their passed text proposal and retrieving their original 2 ADA deposit

Governance: Execute Propose Asset Execute a passed proposal adopted by the DAO to whitelist a new iAsset

Type	Amount	Description
Redeemer	N.A.	Execute
Consume	1	Upgrade UTXO containing the Upgrade Token for the passed proposal
Burn	1	Upgrade Token
Mint	1	iAsset Token
Mint	1	Stability Pool Token
Output	1	iAsset UTXO representing the new whitelisted iAsset
Output	1	Stability Pool UTXO representing the Stability Pool for the new whitelisted iAsset

Governance: Migrate Asset Execute a passed proposal adopted by the DAO to update an existing iAsset

Type	Amount	Description
Redeemer	N.A.	Execute
Redeemer	N.A.	UpgradeAsset
Consume	1	Upgrade UTXO containing the Upgrade Token for the passed proposal
Consume	1	iAsset UTXO representing the iAsset to update
Burn	1	Upgrade Token

Type	Amount	Description
Output	1	iAsset UTXO representing the updated iAsset

3.5 Liquidity

This contract is meant to be a store for the LP Tokens for tracking INDY token rewards. Users will store their LP Tokens meant for reward gathering in this contract. An off-chain mechanism will then be used to calculate and confirm user rewards.

Table 44: Liquidity outputs

Type	Description	Datum
Liquidity	This output acts as a store of LP Tokens	<i>owner</i> : The owner of the Liquidity Position

3.5.1 Liquidity Endpoints

Liquidity: Create Creates a user's liquidity position

Type	Amount	Description
Consume	1+	UTXOs containing the user's LP Tokens to be staked
Output	1	Liquidity UTXO representing the user's staked LP Tokens

Liquidity: Stake Adds more LP Tokens to a user's liquidity position

Type	Amount	Description
Consume	1	Liquidity UTXO representing the user's staked LP Tokens
Consume	1+	UTXOs containing the user's LP Tokens to be staked
Output	1	Liquidity UTXO representing the user's staked LP Tokens

Liquidity: Unstake Unstakes a user's staked LP Tokens

Type	Amount	Description
Consume	1	Liquidity UTXO representing the user's staked LP Tokens
Output	1	UTXO holding the user's unstaked LP Tokens

3.6 Collector

The Collector contract is an intermediary contract between protocol fee collection and distribution. The collection of funds can occur by sending funds directly to the Collector, or consuming an existing Collector and the output being more funds than were input. To distribute the funds, the Staking Manager can consume a Collector UTXO and use it to send funds to INDY stakers.

3.6.1 Parameters

- `stakingManagerNFT` :: `StakingManagerNFT`. NFT of StakingManager.
- `stakingToken` :: `StakingToken`. Token for identifying authentic Staking Position output.
- `versionRecordToken` :: `VersionRecordToken`. Token identifying the VersionRegistry output

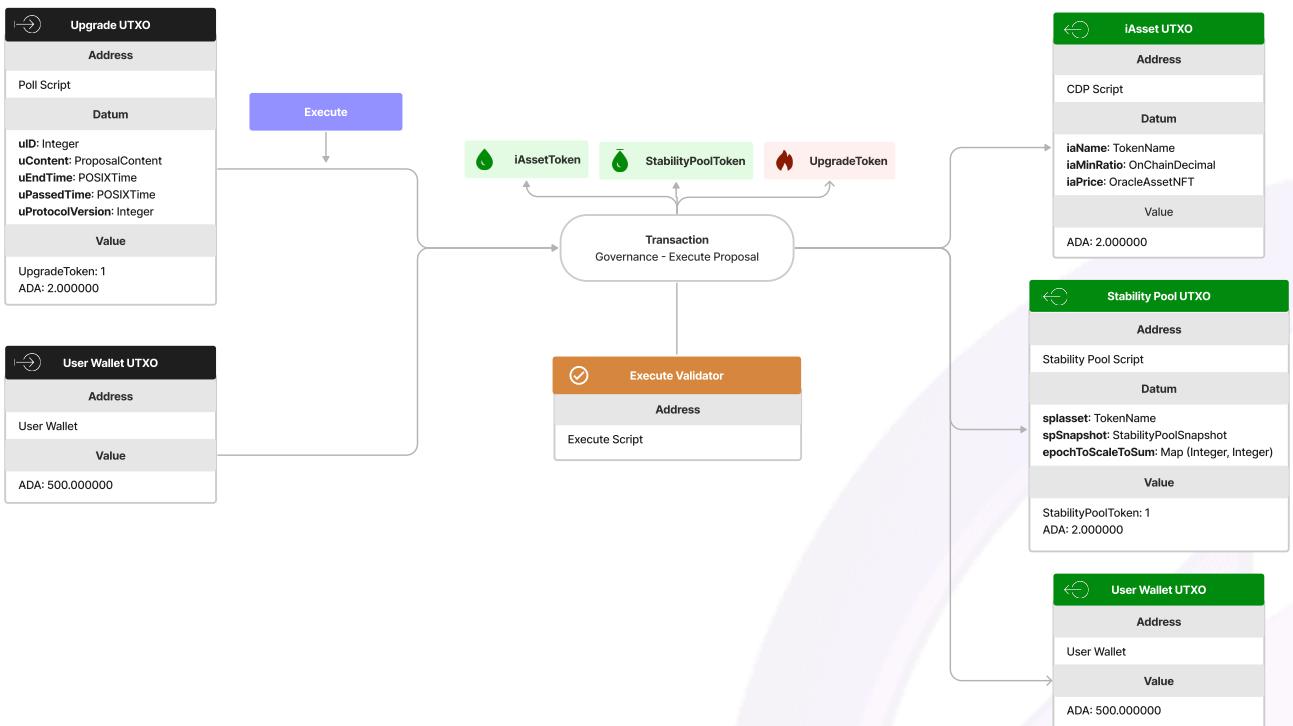

Figure 45: Example of a user executing their passed whitelist iAsset proposal, enabling a new iAsset within the protocol, creating a new Stability Pool, and retrieving their original 2 ADA deposit

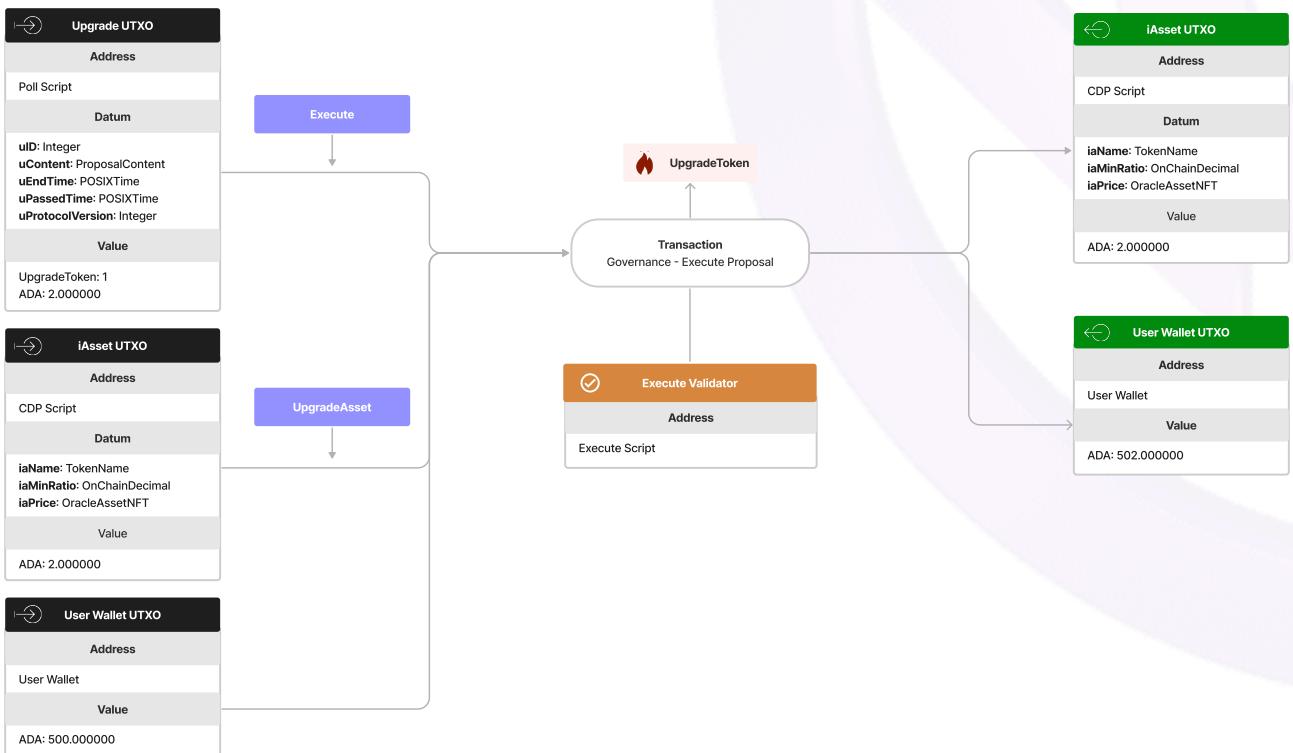

Figure 46: Example of a user executing their passed proposal to update an iAsset, and retrieving their original 2 ADA deposit

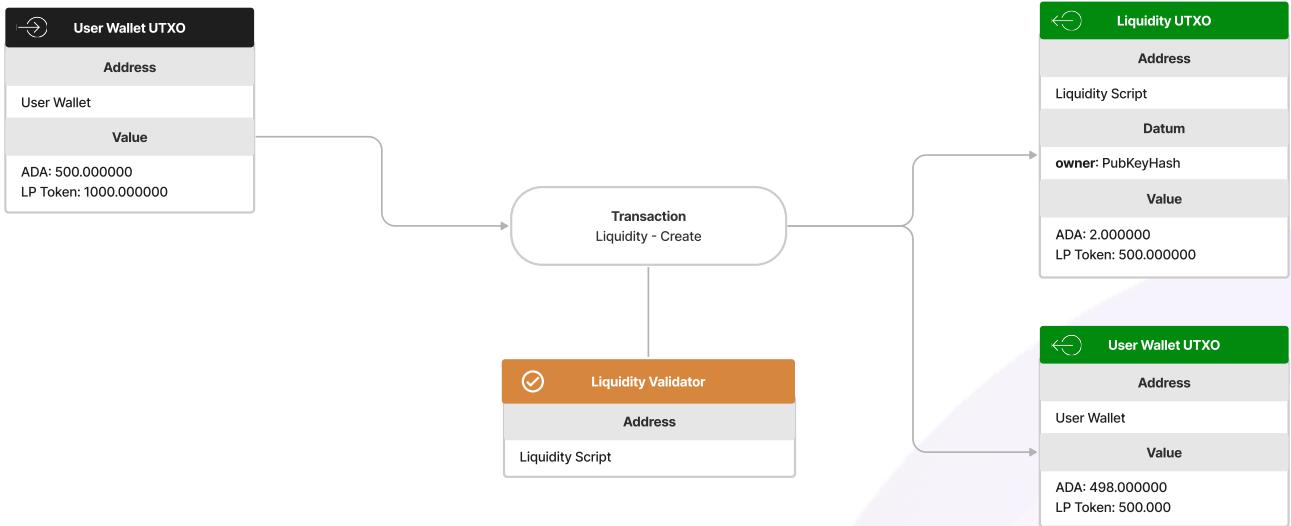

Figure 47: Example of a user staking 500 LP tokens and depositing a refundable 2 ADA

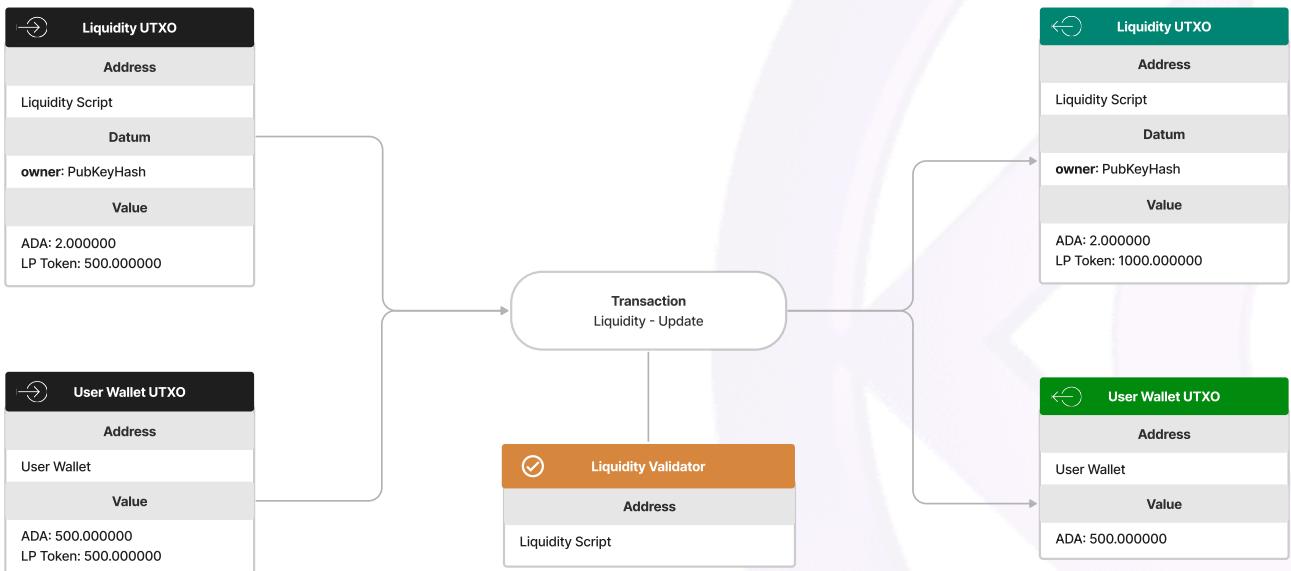

Figure 48: Example of a user staking an additional 500 LP tokens

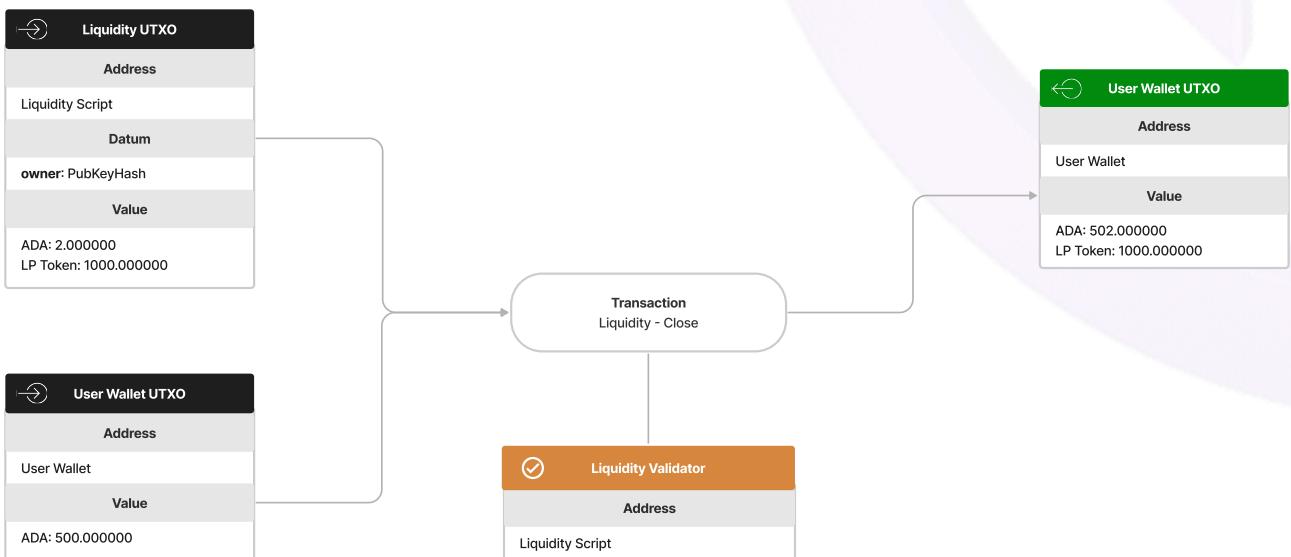

Figure 49: Example of a user unstaking 500 LP tokens and receiving back their 2 ADA deposit

3.6.2 Collector Endpoints

Collector: Collect Collect Protocol Fees upon withdrawing a CDP's collateral or closing a CDP

Type	Amount	Description
Redeemer	N.A.	Collect
Consume	1	Collector UTXO which may already contain previously collected protocol fees
Consume	1	CDP UTXO that represents a user's CDP
Output	1	Collector UTXO updated with the collected fee

3.7 Treasury

The purpose of this contract is to hold the DAO Treasury funds. The DAO Treasury will contain INDY that's vested over time according to Indigo's tokenomics model. The funds in the DAO Treasury are intended to be spent to help further develop, maintain and enhance the Indigo Protocol for the betterment of its users and INDY holders. Until a future protocol version upgrade allows those funds to be spent, the funds will be locked in this contract.

3.7.1 Parameters

- `versionRecordToken :: VersionRecordToken`. Token identifying the VersionRegistry output.

Table 49: Treasury outputs

Type	Description	Values
Treasury	This output stores the DAO Treasury tokens	<i>INDY</i> : The INDY stored in the Treasury <i>IdentityToken</i> : 1

4 Known Protocol Limitations

Indigo Protocol v1.0 was built to support a mainnet launch. However, there are a few areas that could have additional optimizations and/or fixes to be more scalable and to support a growing user base.

4.1 Stability Pool Contention

As described in the [SP Rewards section](#), SPs have two associated UTXOs that can lead to contention: SP state, and account record. There exists one SP state UTXO per iAsset. SP state must be updated upon the following actions:

1. Create an account record (i.e., deposit iAsset into the SP)
2. Adjust an account record (i.e., deposit iAsset into, or withdraw iAsset from, the SP)
3. Liquidate a CDP (i.e., withdraw iAsset from the SP)

Updating SP state causes contention because only one update can be made per SP per block. As a mitigation effort, multiple CDPs can be merged into one to reduce the number of CDP liquidation actions required against a single SP.

Contention still exists for users depositing and withdrawing iAssets from a SP. To mitigate this effect, a [fee mechanism](#) has been implemented to disincentivize SP stakers from updating their positions too frequently. When users create or adjust an account record, they will be required to deposit a minimum amount of ADA, which will be redistributed to all SP stakers.

Additionally, contention is experienced when SP stakers withdraw their owed rewards. Only one user can withdraw ADA rewards earned from liquidations per SP per block.

4.2 Governance Contention

Users can deposit their INDY into the protocol to become **Members** and gain access to privileges such as voting rights and reward collection. The **Staking Manager** UTXO is responsible for managing staking positions of users. The Staking Manager must be updated upon the following actions:

1. Create a staking position (i.e., deposit INDY into governance)
2. Adjust a staking position (i.e., deposit INDY into or withdraw INDY from governance)
3. Deposit staking reward (i.e., collect an ADA protocol fee)
4. Withdraw staking reward (i.e., redeem ADA reward for staking)

Interacting with the Staking Manager causes contention because only one update can be made per block. As a mitigation effort, the **Collector** can bundle staking rewards collected by the protocol to reduce the number of staking reward transactions deposited into the Staking Manager. Contention still exists for INDY stakers depositing or withdrawing INDY or withdrawing ADA rewards.

Additionally, contention exists for recording governance votes. To improve scalability, votes are recorded using **individual shards**. Users can pick unused shards to record their votes. While, theoretically, an unlimited number of shards can be configured, the Cardano blockchain is limited in the number of shards that can record votes per block. If there are insufficient available shards, then users will have to wait for a shard to become available before voting.

Shard collision can occur when two or more users select the same shard to vote with; only one user will succeed with recording the vote, the other users using the same shard will experience transaction errors. If a user explicitly checks for shard availability before submitting a transaction, another user may also select that same shard before the transaction is processed in a block, thereby possibly resulting in collision and transaction failure for either user.

5 Definitions for Mathematical Notations

Throughout this document, references are made to mathematical equations. Below is a summary of notations that may be used and their associated meanings.

5.1 Sets

Values enclosed in { } are a unique assortment of values. Each value is separated by a comma (,).

{10, 20, 30, 40, 50} means five values incrementing in tens, beginning at 10 and ending at 50.

5.2 Summation

The \sum represents a sum of values. It can either be in the form of $\sum x$ or $\sum_{i=1}^n i$.
 $\sum x$ means to sum all values of a set. If x is a set of {1, 2, 3}, then:

$$\sum x = 1 + 2 + 3 = 6$$

$\sum_{i=1}^n i$ means to iterate n times and sum the result of x . i begins at 0 increments until i equals n . If n is 3, then:

$$\sum_{i=1}^n i = 1 + 2 + 3 = 6$$

5.3 Length of Sets

A set enclosed within | | represents the length of the set.

$|x|$ means the length of set x . If x is {5, 10, 15}, then $|x| = 3$ because it contains 3 elements in the set.

5.4 Indexes

A subscript (x_i) represents an associated variable or a value within a set.

If x is a set and i is a number, then x_i means the i^{th} element of the set x . If x is {3, 6, 9}, then x_1 is 3, x_2 is 6, and x_3 is 9. Thus, if i is 2, then x_i is 6 because it's the 2^{nd} element of x .

5.5 Mean of Sets

A set with \bar{x} above it represents the mean (average) of the set.

\bar{x} means the mean of set x , which is the sum of all elements in the set divided by the length of the set.
Alternatively, \bar{x} can be expressed as:

$$\frac{\sum_{i=1}^{|x|} x_i}{|x|}$$

If x is $\{10, 30, 20, 40\}$, then:

$$\bar{x} = \frac{10 + 30 + 20 + 40}{4} = 25$$

5.6 Rounding

Values enclosed in $\lceil \rceil$ or $\lfloor \rfloor$ represent the value either rounded up or down to the nearest whole number.

$\lceil x \rceil$ means “ceil,” or to round up to the nearest whole number. If x is 0.5, then: $\lceil x \rceil = 1$.

$\lfloor x \rfloor$ means “floor,” or to round down to the nearest whole number. If x is 0.5, then: $\lfloor x \rfloor = 0$.

5.7 Scoped Variables

Sometimes equations may be simplified and made more readable using scoped variables.

$x = \begin{pmatrix} \text{let } y \text{ equal 1} \\ y \end{pmatrix}$ means to create a variable called y with a value of 1, which can then be referenced throughout any component within the $()$ it's defined within. Therefore, x is 1 because the bottom-most statement is y and y is 1.

5.8 Conditional Statements

A statement proceeding $\{$ without an enclosing $\}$ is conditional. Conditional statements take the form of $\begin{cases} x & \text{if } a > 0 \\ y & \text{otherwise} \end{cases}$. They can have two or more conditions, such as: $\begin{cases} x & \text{if } a > 0 \text{ and } a < 1 \\ y & \text{if } a > 50 \\ z & \text{otherwise} \end{cases}$.

$\begin{cases} x & \text{if } a > 0 \text{ and } a < 1 \\ y & \text{if } a \geq 1 \\ z & \text{otherwise} \end{cases}$ means that the value is determined by the truthfulness of three conditions. If a is between 0 and 1, then the statement is x . If a is 1 or larger, then the statement is y . The only other possibility is a is 0 or smaller, in which case the statement is z .

“otherwise” means if no other condition matches.

“and” means that both conditions must be true.

“or” means that either condition must be true.

5.9 Functions

Statements proceeding $f : () \mapsto$ represent a callable function that can be referenced.

$f : (a, b) \mapsto a + b$ means that f takes two values and adds them together to determine the value. A reference to $f(1, 2)$ equates to 3.

5.10 Minimum and Maximums

Minimum and maximum values within sets can be referenced using $\min \{ \}$ and $\max \{ \}$ respectively.

$\min \{100, 10, 1000\}$ means the lowest value out of the set $\{100, 10, 1000\}$, therefore: 10.

$\max \{100, 10, 1000\}$ means the highest value out of the set $\{100, 10, 1000\}$, therefore: 1000.

6 Minimum ADA to Create UTXO

To create a UTXO on Cardano, a minimum amount of ADA is required to be locked into the transaction. The amount of ADA deposit required to create a UTXO is calculated using the formula:

$$x = ab + 160b$$

Where:

- x is the amount of ADA required to create a shard
- a is the size of the UTXO of the transaction
- b is the *coinsPerUTxOByte* parameter of the Cardano blockchain¹⁵

Upon closing the UTXO, the deposited ADA can be unlocked.

¹⁵Calculating required ADA for UTXOs is described by the UTXO inference rules on page 16 of the [formal Cardano specification](#).
